  ### 7.25.11.54 CINSTRCONF

Address offset: 0x634

Custom instruction configuration register.

A new custom instruction is sent every time this register is written. The READY event will be generated when the custom instruction has been sent.

## 7.26 RADIO — 2.4 GHz radio

The 2.4 GHz radio transceiver is compatible with multiple radio standards such as Bluetooth Low Energy, IEEE 802.15.4, and Nordic's proprietary modes.

The main features of RADIO are:

- Multidomain 2.4 GHz radio transceiver, with
  - Bluetooth Low Energy 1 Mbps and 2 Mbps modes
  - Bluetooth Low Energy Long Range (125 kbps and 500 kbps) modes
  - Angle of Arrival (AoA) and Angle of Departure (AoD) direction finding using Bluetooth Low Energy
  - IEEE 802.15.4 250 kbps mode
  - 1 Mbps and 2 Mbps Nordic proprietary modes
- Best in class link budget and low power operation
- Efficient data interface with EasyDMA support
- Automatic address filtering and pattern matching

EasyDMA, in combination with an automated packet assembler, packet disassembler, automated CRC generator and CRC checker, makes it easy to configure and use RADIO. See the following figure for details.

Figure 146: RADIO block diagram

RADIO includes a device address match unit and an interframe spacing control unit that can be utilized to simplify device filtering and interframe spacing in Bluetooth Low Energy and similar applications.

RADIO also includes a received signal strength indicator (RSSI) and a bit counter. The bit counter generates events when a preconfigured number of bits are sent or received by RADIO.

### 7.26.1 Packet configuration

A RADIO packet contains the fields PREAMBLE, ADDRESS, S0, LENGTH, S1, PAYLOAD, and CRC. For Long Range (125 kbps and 500 kbps) Bluetooth Low Energy modes, fields CI, TERM1, and TERM2 are also included.

The content of a RADIO packet is illustrated in the following figures. RADIO sends the fields in the packet according to the sequence shown in the figures, starting on the left.

Figure 147: On-air packet layout

Figure 148: On-air packet layout for Long Range (125 kbps and 500 kbps) Bluetooth Low Energy modes

Not shown in the figures is the static payload add-on (the length of which is defined in `PCNF1.STATLEN`, and which is 0 bytes in a standard BLE packet). The static payload add-on is sent between PAYLOAD and CRC fields. RADIO sends the different fields in the packet in the order they are illustrated above, from left to right.

PREAMBLE is sent with least significant bit first on air. The size of the PREAMBLE depends on the mode selected in the `MODE` register:

- The PREAMBLE is one byte for `MODE = Ble_1Mbit` as well as all Nordic proprietary operating modes (`MODE = Nrf_1Mbit` and `MODE = Nrf_2Mbit`), and `PCNF0.PLEN` has to be set accordingly. If the first bit of the ADDRESS is 0, the preamble will be set to 0xAA. Otherwise the PREAMBLE will be set to 0x55.

- For **MODE** = Ble\_2Mbit, the PREAMBLE must be set to 2 bytes through **PCNF0.PLEN**. If the first bit of the ADDRESS is 0, the preamble will be set to 0xAAAA. Otherwise the PREAMBLE will be set to 0x5555.
- For **MODE** = Ble\_LR125Kbit and **MODE** = Ble\_LR500Kbit, the PREAMBLE is 10 repetitions of 0x3C.
- For **MODE** = leee802154\_250Kbit, the PREAMBLE is 4 bytes and set to all zeros.

Radio packets are stored in memory inside instances of a RADIO packet data structure as illustrated below. The PREAMBLE, ADDRESS, CI, TERM1, TERM2, and CRC fields are omitted in this data structure. Fields S0, LENGTH, and S1 are optional.

Figure 149: Representation of a RADIO packet in RAM

The byte ordering on air is always least significant byte first for the ADDRESS and PAYLOAD fields, and most significant byte first for the CRC field. The ADDRESS fields are always transmitted and received least significant bit first. The CRC field is always transmitted and received most significant bit first. The endianness, i.e. the order in which the bits are sent and received, of the S0, LENGTH, S1, and PAYLOAD fields can be configured via **PCNF1.ENDIAN**.

The sizes of the S0, LENGTH, and S1 fields can be individually configured via **S0LEN**, **LLEN**, and **S1LEN** in **PCNF0** respectively. If any of these fields are configured to be less than 8 bits, the least significant bits of the fields are used.

If S0, LENGTH, or S1 are specified with zero length, their fields will be omitted in memory. Otherwise each field will be represented as a separate byte, regardless of the number of bits in their on-air counterpart.

Independent of the configuration of **PCNF1.MAXLEN**, the combined length of S0, LENGTH, S1, and PAYLOAD cannot exceed 258 bytes.

## 7.26.2 Address configuration

The on-air radio ADDRESS field is composed of two parts, the base address field and the address prefix field.

The size of the base address field is configurable via **PCNF1.BALEN**. The base address is truncated from the least significant byte if the **PCNF1.BALEN** is less than 4. See [Definition of logical addresses](#) on page 494.

The on-air addresses are defined in the **BASE0/BASE1** and **PREFIX0/PREFIX1** registers. It is only when writing these registers that the user must relate to the actual on-air addresses. For other radio address registers, such as the **TXADDRESS**, **RXADDRESSES**, and **RXMATCH** registers, logical radio addresses ranging from 0 to 7 are being used. The relationship between the on-air radio addresses and the logical addresses is described in the following table.

| Logical address | Base address | Prefix byte |
|-----------------|--------------|-------------|
| 0               | BASE0        | PREFIX0.AP0 |
| 1               | BASE1        | PREFIX0.AP1 |
| 2               | BASE1        | PREFIX0.AP2 |
| 3               | BASE1        | PREFIX0.AP3 |
| 4               | BASE1        | PREFIX1.AP4 |
| 5               | BASE1        | PREFIX1.AP5 |
| 6               | BASE1        | PREFIX1.AP6 |
| 7               | BASE1        | PREFIX1.AP7 |

Table 50: Definition of logical addresses

### 7.26.3 Data whitening

RADIO can do packet whitening and de-whitening which is enabled in [PCNF1.WHITEN](#). When enabled, whitening and de-whitening will be handled by RADIO automatically as packets are sent and received.

The whitening word is generated using polynomial  $g(D) = D^7 + D^4 + 1$ , which then is XORed with the data packet that is to be whitened, or de-whitened. The linear feedback shift register is initialized via [DATAWHITEIV](#). See the following figure.

Figure 150: Data whitening and de-whitening

Whitening and de-whitening will be performed over the whole packet except for the preamble and the address fields.

Including the address field in CRC check ([CRCNF.SKIPADDR](#)=Include) is not supported for whitened packets.

### 7.26.4 CRC

The CRC generator in RADIO calculates the CRC over the whole packet excluding the preamble.

If useful, the address field can be excluded from the CRC calculation as well. See the [CRCNF](#) register for more information.

The CRC polynomial is configurable as illustrated in the following figure, where bit 0 in the [CRCPOLY](#) register corresponds to  $X^0$  and bit 1 corresponds to  $X^1$  etc. See [CRCPOLY](#) on page 551 for more information.

Figure 151: CRC generation of an  $n$  bit CRC

The figure shows that the CRC is calculated by feeding the packet serially through the CRC generator. Before the packet is clocked through the CRC generator, the CRC generator's latches  $b_0$  through  $b_n$  will be initialized with a predefined value specified in the [CRCINIT](#) register. After the whole packet has been clocked through the CRC generator,  $b_0$  through  $b_n$  will hold the resulting CRC. This value will be used by RADIO during both transmission and reception. Latches  $b_0$  through  $b_n$  are not available to be read by the CPU at any time. However, a received CRC can be read by the CPU via the [RXCRC](#) register.

The length ( $n$ ) of the CRC is configurable, see [CRCNF](#) for more information.

Once the entire packet, including the CRC, has been received and no errors were detected, RADIO generates a **CRCOK** event. If CRC errors were detected, a **CRCERROR** event is generated.

The status of the CRC check can be read from the **CRCSTATUS** register after a packet has been received.

### 7.26.5 Radio states

Tasks and events are used to control the operating state of RADIO.

RADIO can enter the states described in the following table.

| State     | Description                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------|
| DISABLED  | No operations are going on inside RADIO and the power consumption is at a minimum                    |
| RXRU      | RADIO is ramping up and preparing for reception                                                      |
| RXIDLE    | RADIO is ready for reception to start                                                                |
| RX        | Reception has been started and the addresses enabled in the RXADDRESSES register are being monitored |
| TXRU      | RADIO is ramping up and preparing for transmission                                                   |
| TXIDLE    | RADIO is ready for transmission to start                                                             |
| TX        | RADIO is transmitting a packet                                                                       |
| RXDISABLE | RADIO is disabling the receiver                                                                      |
| TXDISABLE | RADIO is disabling the transmitter                                                                   |

Table 51: RADIO state diagram

A state diagram showing an overview of RADIO is shown in the following figure.

Figure 152: Radio states

This figure shows how the tasks and events relate to RADIO's operation. RADIO does not prevent a task from being triggered from the wrong state. If a task is triggered from the wrong state, for example if the **RXEN** task is triggered from the **RXDISABLE** state, this may lead to incorrect behavior. The **PAYLOAD** event is always generated even if the payload is zero.

The **END** to **START** shortcut should not be used with IEEE 802.15.4 250 kbps mode. Use the **PHYEND** to **START** shortcut instead.

The **END** to **START** shortcut should not be used with Long Range (125 kbps and 500 kbps) Bluetooth Low Energy modes. Use the **PHYEND** to **START** shortcut instead.

### 7.26.6 Transmit sequence

Before RADIO can transmit a packet, it must first ramp-up in TX mode. See TXRU in [Radio states](#) on page 496 and [Transmit sequence](#) on page 497. A TXRU ramp-up sequence is initiated when the **TXEN** task is triggered. After RADIO has successfully ramped up it will generate the **READY** event indicating that a packet transmission can be initiated. A packet transmission is initiated by triggering the **START** task. The **START** task can first be triggered after RADIO has entered into the TXIDLE state.

The following figure illustrates a single packet transmission where the CPU manually triggers the different tasks needed to control the flow of RADIO, i.e. no shortcuts are used. If shortcuts are not used, a certain amount of delay caused by CPU execution is expected between **READY** and **START**, and between **END** and **DISABLE**. As illustrated in the following figure, RADIO will by default transmit 1s between **READY** and **START**, and between **END** and **DISABLED**. What is transmitted can be programmed through the DTX field in the **MODECNF0** register.

Figure 153: Transmit sequence

The following figure shows a slightly modified version of the transmit sequence where RADIO is configured to use shortcuts between **READY** and **START**, and between **END** and **DISABLE**, which means that no delay is introduced.

Figure 154: Transmit sequence using shortcuts to avoid delays

RADIO is able to send multiple packets one after the other without having to disable and re-enable RADIO between packets, as illustrated in the following figure.

Figure 155: Transmission of multiple packets

### 7.26.7 Receive sequence

Before RADIO is able to receive a packet, it must first ramp up in RX mode. See RXRU in [Radio states](#) on page 496 and [Receive sequence](#) on page 498 for more information.

An RXRU ramp up sequence is initiated when the [RXEN](#) task is triggered. After RADIO has successfully ramped up it will generate the [READY](#) event indicating that a packet reception can be initiated. A packet reception is initiated by triggering the [START](#) task. As illustrated in [Radio states](#) on page 496, the [START](#) task can first be triggered after RADIO has entered into the RXIDLE state.

The following figure shows a single packet reception where the CPU manually triggers the different tasks needed to control the flow of RADIO, i.e. no shortcuts are used. If shortcuts are not used, a certain amount of delay caused by CPU execution is expected between [READY](#) and [START](#), and between [END](#) and [DISABLE](#). RADIO will be listening and possibly receiving undefined data, represented with an 'X', from [START](#) and until a packet with valid preamble (P) is received.

Figure 156: Receive sequence

The following figure shows a modified version of the receive sequence, where RADIO is configured to use shortcuts between [READY](#) and [START](#), and between [END](#) and [DISABLE](#), which means that no delay is introduced.

Figure 157: Receive sequence using shortcuts to avoid delays

RADIO can receive consecutive packets without having to disable and re-enable RADIO between packets, as illustrated in the following figure.

Figure 158: Reception of multiple packets

### 7.26.8 Received signal strength indicator (RSSI)

RADIO implements a mechanism for measuring the power in the received signal. This feature is called received signal strength indicator (RSSI).

The RSSI is measured continuously and the value filtered using a single-pole IIR filter. After a signal level change, the RSSI will settle after approximately `RSSISETTLE`.

Sampling of the received signal strength is started by using the `RSSISTART` task. The sample can be read from the `RSSISAMPLE` register.

The sample period of the RSSI is defined by `RSSI_PERIOD`. The `RSSISAMPLE` will hold the filtered received signal strength after this sample period.

For the RSSI sample to be valid, RADIO has to be enabled in RX mode (`RXEN` task) and the reception has to be started (`READY` event followed by `START` task).

### 7.26.9 Interframe spacing (IFS)

Interframe spacing (IFS) is defined as the time, in microseconds, between two consecutive packets, starting from when the end of the last bit of the previous packet is received, to the beginning of the first bit of the subsequent packet that is transmitted.

RADIO can enforce this interval, as specified in the `TIFS` register, as long as the `TIFS` register is not specified to be shorter than RADIO's turnaround time (i.e. the time needed to switch off the receiver, and then

switch the transmitter back on). The **TIFS** register can be written any time before the last bit on air is received.

This timing is illustrated in the following figure.

Figure 159: IFS timing detail

The TIFS duration starts after the last bit on air (just before the **END** event), and elapses with the first bit being transmitted on air (just after **READY** event).

TIFS is only enforced if the shortcuts **END** to **DISABLE** and **DISABLED** to **TXEN** or **END** to **DISABLE** and **DISABLED** to **RXEN** are enabled.

TIFS is qualified for use in IEEE 802.15.4 250kbps mode, Bluetooth Low Energy Long Range (125 kbps and 500 kbps) modes, and Bluetooth Low Energy 1 Mbps and 2 Mbps modes, using the default ramp-up mode.

**SHORTS** and **TIFS** registers are not double-buffered, and can be updated at any point before the last bit on air is received. The **MODE** register is double-buffered and sampled at the **TXEN** or **RXEN** task.

### 7.26.10 Device address match

The device address match feature is tailored for device filtering in Bluetooth Low Energy and similar implementations.

This feature enables on-the-fly device address matching while receiving a packet on air. This feature only works in receive mode and when RADIO is configured for little endian, see **PCNF1.ENDIAN** for more information.

The device address match unit assumes that the first 48 bits of the payload are the device address and that bit number 6 in S0 is the TxAdd bit. See the *Bluetooth Core Specification* for more information about device addresses, TxAdd, and device filtering procedure.

RADIO is able to listen for eight different device addresses at the same time. These addresses are specified in a DAB/DAP register pair, one pair per address, in addition to a TxAdd bit configured in the DACNF register. The DAB register specifies the 32 least significant bits of the device address, while the DAP register specifies the 16 most significant bits of the device address.

Each of the device addresses can be individually included or excluded from the matching mechanism. This is configured in the **DACNF** register.

### 7.26.11 Bit counter

RADIO implements a simple counter that can be configured to generate an event after a specific number of bits have been transmitted or received.

By using shortcuts, this counter can be started from different events generated by RADIO and count relative to these.

The bit counter is started by triggering the **BCSTART** task, and stopped by triggering the **BCSTOP** task. A **BCMATCH** event will be generated when the bit counter has counted the number of bits specified in the **BCC** register. The bit counter will continue to count bits until the **DISABLED** event is generated or until the **BCSTOP** task is triggered. After a **BCMATCH** event, the CPU can reconfigure the **BCC** value for new **BCMATCH** events within the same packet.

The bit counter can only be started after RADIO has received the **ADDRESS** event.

The bit counter will stop and reset on either the **BCSTOP**, **STOP**, or **DISABLE** task, or the **END** event.

The following figure shows how the bit counter can be used to generate a **BCMATCH** event in the beginning of the packet payload, and again generate a second **BCMATCH** event after sending 2 bytes (16 bits) of the payload.

Figure 160: Bit counter example

### 7.26.12 Direction finding

RADIO implements the Angle of Arrival (AoA) and Angle of Departure (AoD) Bluetooth Low Energy feature, which can be used to determine the direction of a peer device. The feature is available for the Bluetooth Low Energy 1 and 2 Mbps modes.

When using this feature, the transmitter sends a packet with a constant tone extension (CTE) appended to the packet, after the CRC. During the CTE, the receiver can take IQ samples of the incoming signal.

An antenna array is employed at the transmitter (AoD) or at the receiver (AoA). The AoD transmitter, or AoA receiver, switches between the antennas, in order to collect IQ samples from the different antenna pairs. The IQ samples can be used to calculate the relative path lengths between the antenna pairs, which can be used to estimate the direction of the transmitter.

#### 7.26.12.1 CTE format

The CTE is from 16  $\mu$ s to 160  $\mu$ s and consists of an unwhitened sequence of 1s, equivalent to a continuous tone nominally offset from the carrier by +250 kHz for the Bluetooth Low Energy 1 Mbps PHY and +500

kHz for the 2 Mbps Bluetooth Low Energy PHY. The format of the CTE, when switching and/or sampling, is shown in the following figure.

Figure 161: Constant tone extension (CTE) structure

Antenna switching is performed during switch slots and the guard period. The AoA/AoD feature requires that one IQ sample is taken for each microsecond within the reference period, and once for each sample slot. Oversampling is possible by changing the sample spacing as described in [IQ sampling](#) on page 505. The switch slot and sample slot durations are either 1 or 2  $\mu\text{s}$ , but must be equal. The format of the CTE and switching and sampling procedures may be configured prior to, or during, packet transmission and reception. Alternatively, during packet reception, these operations can be configured by reading specific fields of the packet contents.

### 7.26.12.2 Mode

Depending on the [DFEMODE](#), the device performs the procedures shown in the following table.

|                   |                                           | DFEMODE |    |     |    |
|-------------------|-------------------------------------------|---------|----|-----|----|
|                   |                                           | AOA     |    | AOD |    |
|                   |                                           | TX      | RX | TX  | RX |
| AoA/AoD Procedure | Generating and transmitting CTE           | x       |    | x   |    |
|                   | Receiving, interpreting, and sampling CTE |         | x  |     | x  |
|                   | Antenna switching                         |         | x  | x   |    |

Table 52: AoA/AoD Procedures performed as a function of DFEMODE and TX/RX mode

### 7.26.12.3 Inline configuration

When inline configuration is enabled during RX, further configuration of the AoA/AoD procedures is performed based on the values of the CP bit and the CTEInfo octet within the packet. This is enabled by setting [CTEINLINECONF.CTEINLINECTRLIN](#). The CTEInfo octet is present only if the CP bit is set. The position of the CP bit and CTEInfo octet depends on whether the packet has a *Data Channel PDU* ([CTEINLINECONF.CTEINFOINS1](#)=InS1), or an *Advertising Channel PDU* ([CTEINLINECONF.CTEINFOINS1](#)=NotInS1).

#### Data channel PDU

For Data Channel PDUs, [PCNF0.SOLEN](#) must be 1 byte, and [PCNF0.LFLEN](#) must be 8 bits. To determine if S1 is present, the registers [CTEINLINECONF.S0MASK](#) and [CTEINLINECONF.S0CONF](#) forms a bitwise mask-and-test for the S0 field. If the bitwise AND between S0 and S0MASK equals S0CONF, then S1 is determined to be present. When present, the value of [PCNF0.S1LEN](#) will be ignored, as this is decided by the CP bit in the the following figure.

Figure 162: Data channel PDU header

When encrypting and decrypting Bluetooth Low Energy packets using the [CCM](#) peripheral, it is also required to set [PCNF0.S1INCL](#)=1. The CCM mode must be configured to use an 8-bit length field. The value of the CP bit is included in the calculation of the MIC, while the S1 field is ignored by the CCM calculation.

## Advertising channel PDU

For advertising channel PDUs, the CTEInfo Flag replaces the CP bit. The CTEInfo Flag is within the extended header flag field in some of the advertising PDUs that employ the common extended advertising payload format (i.e. [AUX\\_SYNC\\_IND](#), [AUX\\_CHAIN\\_IND](#)). The format of such packets is shown in the following figure.

Figure 163: Advertising channel PDU header

The [CTEINLINECONF.S0CONF](#) and [CTEINLINECONF.S0MASK](#) fields can be configured to accept only certain advertising PDU Types. If the extended header length is non-zero, the CTEInfo extended header flag is checked to determine whether CTEInfo is present. If a bit before the CTEInfo flag within the extended header flags is set, then the CTEInfo position is postponed 6 octets.

## CTEInfo parsing

The CTEInfo field is shown in the following figure.

Figure 164: CTEInfo field

The CTETIME field defines the length of the CTE in 8  $\mu$ s units. The valid upper bound of values can be adjusted using [CTEINLINECONF.CTETIMEVALIDRANGE](#), including allowing use of the RFU bit within this field. If the CTETIME field is an invalid value of either 0 or 1, the CTE is assumed to be the minimum valid length of 16  $\mu$ s. The slot duration is determined by the CTEType field. In RX mode this determines whether the sample spacing as defined in [CTEINLINECONF.CTEINLINERXMODE1US](#) or [CTEINLINECONF.CTEINLINERXMODE2US](#) is used.

| CTEType | Description             | TX switch spacing | RX sample spacing during reference period | Sample spacing RX during reference period |
|---------|-------------------------|-------------------|-------------------------------------------|-------------------------------------------|
| 0       | AoA, no switching       | -                 | TSAMPLESPACING1                           | TSAMPLESPACING2                           |
| 1       | AoD, 1 $\mu$ s slots    | 2 $\mu$ s         | TSAMPLESPACING1                           | CTEINLINERXMODE1US                        |
| 2       | AoD, 2 $\mu$ s slots    | 4 $\mu$ s         | TSAMPLESPACING1                           | CTEINLINERXMODE2US                        |
| 3       | Reserved for future use |                   |                                           |                                           |

Table 53: Switching and sampling spacing based on CTEType

### 7.26.12.4 Manual configuration

If [CTEINLINECONF.CTEINLINECTRLLEN](#) is not set, then the packet is not parsed to determine the CTE parameters and the antenna switching and sampling is controlled by other registers (see [Antenna switching](#) on page 504). The length of the CTE is given in 8  $\mu$ s units by [DFECTRL1.NUMBEROF8US](#). The start of the antenna switching and/or sampling (denoted as an AoA/AoD procedure), can be configured to start at some trigger with an additional offset. Using [DFECTRL1.DFEINEXTENSION](#), the trigger can be

configured to be the end of the CRC, or alternatively, the ADDRESS event. The additional offset for antenna switching is configured using [DFECTRL2.TSWITCHOFFSET](#). Similarly, the additional offset for antenna sampling is configured using [DFECTRL2.TSAMPLEOFFSET](#).

### 7.26.12.5 Receive- and transmit sequences

The addition of the CTE to the transmitted packet is illustrated in the following figure.

Figure 165: Transmit sequence with DFE

The presence of CTE within a received packet is signalled by the [CTEPRESENT](#) event illustrated in the following figure.

Figure 166: Receive sequence with DFE

### 7.26.12.6 Antenna switching

RADIO can control up to 8 GPIO pins in order to control external antenna switches used in direction finding.

#### Pin configuration

The eight antenna selection signals are mapped to physical pins according to the pin numbers specified in the [PSEL.DFEGPIO\[n\]](#) registers. Only pins that have the [PSEL.DFEGPIO\[n\].CONNECTED](#) field set to Connected will be controlled by RADIO. Pins that are disconnected will be controlled by GPIO.

During transmission in AoD TX mode or reception in AoA RX mode, RADIO automatically acquires the pins as needed. At times when RADIO does not use the pin, the pin is released to its default state and controlled by the [GPIO](#) configuration. Thus, the pin must be configured using the [GPIO](#) peripheral.

| Pin acquired by RADIO | Direction                         | Value                                      | Comment                                                                                |
|-----------------------|-----------------------------------|--------------------------------------------|----------------------------------------------------------------------------------------|
| Yes                   | Output                            | Specified in <a href="#">SWITCHPATTERN</a> | Pin acquired by RADIO, and in use for DFE.                                             |
| No                    | Specified by <a href="#">GPIO</a> | Specified by <a href="#">GPIO</a>          | DFE not in progress. Pin has not been acquired by RADIO, but is available for DFE use. |

Table 54: Pin configuration matrix for a connected and enabled pin [n]

## Switch pattern configuration

The values of the GPIOs while switching during the CTE are configured by writing successively to the [SWITCHPATTERN](#) register. The first write to [SWITCHPATTERN](#) is the GPIO pattern applied from the call of [TASKS\\_TXEN](#) or [TASKS\\_RXEN](#) until the first antenna switch is triggered. The second write sets the pattern for the reference period and is applied at the start of the guard period. The following writes set the pattern for the remaining switch slots and are applied at the start of each switch slot. If writing beyond the total number of antenna slots, the pattern will wrap to [SWITCHPATTERN\[2\]](#) and start over again. During operation, when the end of the [SWITCHPATTERN](#) buffer is reached, RADIO cycles back to [SWITCHPATTERN\[2\]](#). At the end of the AoA/AoD procedure, [SWITCHPATTERN\[0\]](#) is applied to [DFECTRL1.TSWITCHSPACING](#) after the previous antenna switch. The [SWITCHPATTERN](#) buffer can be erased/cleared using [CLEARPATTERN](#).

A minimum number of three patterns must be written to the [SWITCHPATTERN](#) register.

If [CTEINLINECONF.CTEINLINECTRLLEN](#) is not set, then the antenna switch spacing is determined by [DFECTRL1.TSWITCHSPACING](#) (see [Switching and sampling spacing based on CTEType](#) on page 503). [DFECTRL2.TSWITCHOFFSET](#) determines the position of the first switch compared to the configurable start of CTE (see [DFECTRL1.DFEINEXTENSION](#)).

### 7.26.12.7 IQ sampling

RADIO uses DMA to write IQ samples recorded during the CTE to RAM. Alternatively, the magnitude and phase of the samples can be recorded using the [DFECTRL1.SAMPLETYPE](#) field. The samples are written to the location in RAM specified by [DFEPACKET.PTR](#). The maximum number of samples to transfer are specified by [DFEPACKET.MAXCNT](#) and the number of samples transferred are given in [DFEPACKET.AMOUNT](#). The IQ samples are recorded with respect to the RX carrier frequency. The format of the samples is provided in the following table.

| SAMPLETYPE       | Field     | Bits  | Description                                                                                             |
|------------------|-----------|-------|---------------------------------------------------------------------------------------------------------|
| 0: I_Q (default) | Q         | 31:16 | 12 bits signed, sign extended to 16 bits. Out of range samples are saturated at value -32768.           |
|                  | I         | 15:0  |                                                                                                         |
| 1: MagPhase      | reserved  | 31:29 | Always zero                                                                                             |
|                  | magnitude | 28:16 | 13 bits unsigned. Equals $1.646756 \cdot \sqrt{I^2 + Q^2}$ .                                            |
|                  | phase     | 15:0  | 9 bits signed, sign extended to 16 bits. Equals $64 \cdot \text{atan2}(Q, I)$ in the range [-201, 201]. |

Table 55: Format of samples

Oversampling is configured separately for the reference period and for the time after the reference period. During the reference period, the sample spacing is determined by [DFECTRL1.TSAMPLESPACINGREF](#). [DFECTRL2.TSAMPLEOFFSET](#) allows fine tuning the position of the samples in steps of 16 MHz periods (62.5 ns)

For the time after the reference period, if [CTEINLINECONF.CTEINLINECTRLLEN](#) is disabled, the sample spacing is set in [DFECTRL1.TSAMPLESPACING](#). However, when [CTEINLINECONF.CTEINLINECTRLLEN](#) is enabled, the sample spacing is determined by two different registers, depending on whether the device is in AoA or AoD RX-mode.

For AoD RX mode, the sample spacing after the reference period is determined by the CTEType in the packet, as listed in the following table.

| CTEType             | Sample spacing                   |
|---------------------|----------------------------------|
| AoD 1 $\mu$ s slots | CTEINLINECONF.CTEINLINERXMODE1US |
| AoD 2 $\mu$ s slots | CTEINLINECONF.CTEINLINERXMODE2US |
| Other               | DFECTRL1.TSAMPLESPACING          |

Table 56: Sample spacing when CTEINLINECONF.CTEINLINECTRLLEN is set and the device is in AoD RX mode

For AoA RX mode, the sample spacing after the reference period is determined by DFECTRL1.TSWITCHSPACING, as listed in the following table.

| DFECTRL1.TSWITCHSPACING | Sample spacing                   |
|-------------------------|----------------------------------|
| 2 $\mu$ s               | CTEINLINECONF.CTEINLINERXMODE1US |
| 4 $\mu$ s               | CTEINLINECONF.CTEINLINERXMODE2US |
| Other                   | DFECTRL1.TSAMPLESPACING          |

Table 57: Sample spacing when CTEINLINECONF.CTEINLINECTRLLEN is set and the device is in AoA RX mode

For the reference and switching periods, DFECTRL1.TSAMPLESPACINGREF and DFECTRL1.TSAMPLESPACING can be used to achieve oversampling.

### 7.26.13 IEEE 802.15.4 operation

With the `MODE=ieee802154_250kbit`, RADIO will comply with the IEEE 802.15.4-2006 standard implementing its 250 kbps, 2450 MHz, O-QPSK PHY.

The IEEE 802.15.4 standard differs from Nordic's proprietary and Bluetooth Low Energy modes. Notable differences include modulation scheme, channel structure, packet structure, security, and medium access control.

The main features of the IEEE 802.15.4 mode are:

- Ultra-low power 250 kbps, 2450 MHz, IEEE 802.15.4-2006 compliant link
- Clear channel assessment (CCA)
- Energy detection (ED) scan
- CRC generation

#### 7.26.13.1 Packet structure

The IEEE 802.15.4 standard defines an on-the-air frame/packet that is different from what is used in Bluetooth Low Energy.

The following figure provides an overview of the physical frame structure and its timing.

Figure 167: IEEE 802.15.4 frame format (PPDU)

The standard uses the term *octet* for an 8-bit storage unit within the PPDU. For timing, the value *symbol* is used, and it has a duration of 16  $\mu$ s.

The total usable payload (PSDU) is 127 octets, but when CRC is in use, this is reduced to 125 octets of usable payload.

The preamble sequence consists of four octets that are all zero, and are used for synchronizing RADIO's receiver. Following the preamble is the single octet *start of frame delimiter (SFD)*, with a fixed value of 0xA7. An alternate SFD can be programmed through the [SFD](#) register, providing an initial level of frame filtering for those who choose non-standard compliance. It is a valuable feature when operating in a congested or private network. The preamble sequence and the SFD are generated by RADIO, and are not programmed by the user into the frame buffer.

Following the five octet *synchronization header (SHR)* is the single octet *phy header (PHR)*. The least significant seven bits of PHR denote the frame length of the following PSDU. The most significant bit is reserved and is set to 0 for frames that are standard compliant. RADIO reports all eight bits which can be used to carry additional information. The PHR is the first byte written to the frame data memory pointed to by [PACKETPTR](#). Frames with zero length are discarded, and the [FRAMESTART](#) event is not generated in this case.

The next N octets carry the data of the PHY packet, where N equals the value of the PHR. For an implementation also using the IEEE 802.15.4 medium access control (MAC) layer, the PHY data is a MAC frame of N-2 octets, since two octets occupy a CRC field.

An IEEE 802.15.4 MAC layer frame consists of the following:

- A header:
  - The frame control field (FCF)
  - The sequence number
  - Addressing fields
- A payload
- The 16-bit frame control sequence (FCS)

Figure 168: IEEE 802.15.4 frame format (MPDU)

The two FCF octets contain information about the frame type, addressing, and other control flags. This field is decoded when using the assisted operating modes offered by RADIO.

The sequence number is a single octet in size and is unique for a frame. It is used in the associated acknowledgement frame sent upon successful frame reception.

The addressing field can be zero (acknowledgement frame) or up to 20 octets in size. The field is used to direct packets to the correct recipient and denote its origin. IEEE 802.15.4 bases its addressing on networks being organized in PANs with 16-bit identifier and nodes having a 16-bit or 64-bit address. In the assisted receive mode, these parameters are analyzed for address matching and acknowledgement.

The MAC payload carries the data of the next higher layer, or in the case of a MAC command frame, information used by the MAC layer itself.

The two last octets contain the 16-bit ITU-T CRC. The FCS is calculated over the MAC header (MHR) and MAC payload (MSDU) parts of the frame. This field is calculated automatically when sending a frame, or indicated in the [CRCSTATUS](#) register when a frame is received. If configured, this feature is maintained autonomously by the CRC module.

### 7.26.13.2 Operating frequencies

The IEEE 802.15.4 standard defines 16 channels in the 2450 MHz frequency band. The channels are numbered from 11 to 26, and each channel is 5 MHz wide.

To choose the correct channel center frequency, the [FREQUENCY](#) register must be programmed according to the following table.

| IEEE 802.15.4 channel | Center frequency (MHz) | FREQUENCY setting |
|-----------------------|------------------------|-------------------|
| Channel 11            | 2405                   | 5                 |
| Channel 12            | 2410                   | 10                |
| Channel 13            | 2415                   | 15                |
| Channel 14            | 2420                   | 20                |
| Channel 15            | 2425                   | 25                |
| Channel 16            | 2430                   | 30                |
| Channel 17            | 2435                   | 35                |
| Channel 18            | 2440                   | 40                |
| Channel 19            | 2445                   | 45                |
| Channel 20            | 2450                   | 50                |
| Channel 21            | 2455                   | 55                |
| Channel 22            | 2460                   | 60                |
| Channel 23            | 2465                   | 65                |
| Channel 24            | 2470                   | 70                |
| Channel 25            | 2475                   | 75                |
| Channel 26            | 2480                   | 80                |

Table 58: IEEE 802.15.4 center frequency definition

### 7.26.13.3 Energy detection (ED)

As required by the IEEE 802.15.4 standard, it must be possible to sample the received signal power within the bandwidth of a channel, for the purpose of determining presence of activity.

To prevent the channel signal from being decoded, the shortcut between the [READY](#) event and the [START](#) task should be disabled before putting RADIO in receive mode. The energy detection (ED) measurement time, where RSSI samples are averaged, is 8 symbol periods, corresponding to 128  $\mu$ s. The standard further specifies the measurement to be a number between 0 and 255, where 0 shall indicate received power less than 10 dB above the selected receiver sensitivity. The power range of the ED values must be at least a 40 dB linear mapping with accuracy of  $\pm 6$  dB. See section 6.9.7 *Receiver ED* in the IEEE 802.15.4 standard for further details.

The following example shows how to perform a single energy detection measurement and convert to IEEE 802.15.4 scale.

### IEEE 802.15.4 ED measurement example

```
#define ED_RSSISCALE 4 // From electrical specifications
uint8_t sample_ed(void)
{
    int val;
    NRF_RADIO->TASKS_EDSTART = 1; // Start
    while (NRF_RADIO->EVENTS_EDEND != 1) {
        // CPU can sleep here or do something else
        // Use of interrupts are encouraged
    }
    val = NRF_RADIO->EDSAMPLE * ED_RSSISCALE; // Read level
    return (uint8_t)(val>255 ? 255 : val);    // Convert to IEEE 802.15.4 scale
}
```

For scaling between hardware value and dBm, see equation [Conversion between hardware value and dBm](#) on page 511.

The mlme-scan.req primitive of the MAC layer uses the ED measurement to detect channels where there might be wireless activity. To assist this primitive, a tailored mode of operation is available where the ED measurement runs for a defined number of iterations keeping track of the maximum ED level. This is engaged by writing the **EDCNT** register to a value different from 0, where it will run the specified number of iterations and report the maximum energy measurement in the **EDSAMPLE** register. The scan is started with **EDSTART** task and its end indicated with the **EDEND** event. This significantly reduces the interrupt frequency and therefore power consumption. The following figure shows how the ED measurement will operate depending on the **EDCNT** register.

**EDCNT = 0**

**EDCNT = N-1**

Figure 169: Energy detection measurement examples

The scan is stopped by writing the **EDSTOP** task. It is followed by the **EDSTOPPED** event when the module has terminated.

### 7.26.13.4 Clear channel assessment (CCA)

The IEEE 802.15.4 standard implements a listen-before-talk channel access method to avoid collisions when transmitting, known as *carrier sense multiple access with collision avoidance (CSMA-CA)*. The key part of this is measuring if the wireless medium is busy or not.

The following clear channel assesment modes are supported:

- *CCA Mode 1* (energy above threshold) - The medium is reported busy upon detecting any energy above the ED threshold.
- *CCA Mode 2* (carrier sense only) - The medium is reported busy upon detection of a signal compliant with the IEEE 802.15.4 standard with the same modulation and spreading characteristics.
- *CCA Mode 3* (carrier sense with energy above threshold) - The medium is reported busy using a logical combination (AND/OR) between the results from CCA Mode 1 and CCA Mode 2.

The clear channel assessment should survey a period equal to 8 symbols or 128  $\mu$ s.

RADIO must be in RX mode and be able to receive correct packets when performing the CCA. The shortcut between **READY** and **START** must be disabled if baseband processing is not to be performed while the measurement is running.

Register **EDSAMPLE** on page 556 is updated at the end of the clear channel assessment and can be used to read the energy level measured during the procedure. For **CCACTRL.CCAMODE**=EdModeEdModeTest1, **EDSAMPLE** holds the first ED measurement. For the other CCA modes, **EDSAMPLE** holds the average ED value.

## CCA Mode 1

*CCA Mode 1* is enabled by first configuring the field **CCACTRL.CCAMODE**=EdMode and writing the **CCACTRL.CCAEDTHRES** field to a chosen value. Once the **CCASTART** task is written, RADIO will perform an ED measurement for 8 symbols and compare the measured level with that found in the **CCACTRL.CCAEDTHRES** field. If the measured value is higher than or equal to this threshold, the **CCABUSY** event is generated. If the measured level is less than the threshold, the **CCAIDLE** event is generated.

## CCA Mode 2

*CCA Mode 2* is enabled by configuring **CCACTRL.CCAMODE**=CarrierMode. RADIO will sample to see if a valid SFD is found during the 8 symbols. If a valid SFD is detected, the **CCABUSY** event is generated and the device should not send any data. The **CCABUSY** event is also generated if the scan was performed during an ongoing frame reception. In the case where the measurement period completes with no SFD detection, the **CCAIDLE** event is generated. When **CCACTRL.CCACORRCNT** is not zero, the algorithm will look at the correlator output in addition to the SFD detection signal. If a SFD is reported during the scan period, it will terminate immediately indicating busy medium. Similarly, if the number of peaks above **CCACTRL.CCACORRTHRES** crosses the **CCACTRL.CCACORRCNT**, the **CCACTRL.CCABUSY** event is generated. If less than **CCACORRCOUNT** crossings are found and no SFD is reported, the **CCAIDLE** event will be generated and the device can send data.

## CCA Mode 3

*CCA Mode 3* is enabled by configuring **CCACTRL.CCAMODE**=CarrierAndEdMode or **CCACTRL.CCAMODE**=CarrierOrEdMode, performing the required logical combination of the result from CCA Mode 1 and 2. The **CCABUSY** or **CCAIDLE** events are generated by ANDing or ORing the *energy above threshold* and *carrier detection* scans.

## Shortcuts

An ongoing CCA can always be stopped by issuing the **CCASTOP** task. This will trigger the associated **CCASTOPPED** event.

For CCA mode automation, the following shortcuts are available:

- To automatically switch between RX mode (when performing the CCA) and to TX mode where the packet is sent, the shortcut between **CCAIDLE** and **TXEN**, in conjunction with the short between **CCAIDLE** and **STOP** must be used.

- To automatically disable RADIO whenever the CCA reports a busy medium, the shortcut between **CCABUSY** and **DISABLE** can be used.
- To immediately start a CCA after ramping up into RX mode, the shortcut between **RXREADY** and **CCASTART** can be used.

## Conversion

The conversion from a CCAEDTHRES, LQI, or EDSAMPLE value to dBm can be done with the following equation, where  $VAL_{HARDWARE}$  is either CCAEDTHRES, LQI, or EDSAMPLE. LQI and EDSAMPLE are hardware-reported values, while CCAEDTHRES is set by software. Constants ED\_RSSISCALE and ED\_RSSIOFFS are from electrical specifications.

$$P_{RF}[dBm] = ED\_RSSIOFFS + VAL_{HARDWARE}$$

Figure 170: Conversion between hardware value and dBm

The ED\_RSSISCALE constant is used to calculate power in 802.15.4 units (0-255):

$$P_{RF}[802.15.4 \text{ units}] = \text{MIN}(ED\_RSSISCALE \times VAL_{HARDWARE}, 255)$$

Figure 171: Conversion between hardware value and 802.15.4 units (0-255)

### 7.26.13.5 Cyclic redundancy check (CRC)

The IEEE 802.15.4 standard uses a 16-bit ITU-T cyclic redundancy check (CRC) calculated over the MAC header (MHR) and MAC service data unit (MSDU).

The standard defines the following generator polynomial:

$$G(x) = x^{16} + x^{12} + x^5 + 1$$

In RX mode, RADIO will trigger the CRC module when the first octet after the frame length (PHR) is received. The CRC will then update on each consecutive octet received. When a complete frame is received the **CRCSTATUS** register will be updated accordingly and the **CRCOK** or **CRCERROR** events generated. When the CRC module is enabled it will not write the two last octets (CRC) to the frame Data RAM. When transmitting, the CRC will be computed on the fly, starting with the first octet after PHR, and inserted as the two last octets in the frame. The EasyDMA will fetch frame length minus 2 octets from RAM and insert the CRC octets at their correct positions in the frame.

The following code shows how to configure the CRC module for correct operation when in IEEE 802.15.4 mode. The **CRC CNF** is written to 16-bit CRC and the **CRC POLY** is written to 0x11021. The start value used by IEEE 802.15.4 is 0 and **CRC INIT** is configured to reflect this.

```
/* 16-bit CRC with ITU-T polynomial with 0 as start condition*/
NRF_RADIO->CRCCNF = ((RADIO_CRCCNF_SKIPADDR_Ieee802154 << RADIO_CRCCNF_SKIPADDR_Pos) |
                    (RADIO_CRCCNF_LEN_Two << RADIO_CRCCNF_LEN_Pos));
NRF_RADIO->CRCPOLY = 0x11021;
NRF_RADIO->CRCINIT = 0;
```

The ENDIANESS subregister must be set to little-endian since the FCS field is transmitted from left bit to right.

### 7.26.13.6 Transmit sequence

The transmission is started by first putting RADIO in RX mode and triggering the **RXEN** task.

An outline of the IEEE 802.15.4 transmission is illustrated in the following figure.

Figure 172: IEEE 802.15.4 transmit sequence

The receiver will ramp up and enter the RXIDLE state where the **READY** event is generated. Upon receiving the ready event, the CCA is started by triggering the **CCASTART** task. The chosen mode of assessment (**CCACTRL.CCAMODE** register) will be performed and signal the **CCAIDLE** or **CCABUSY** event 128  $\mu$ s later. If the **CCABUSY** event is received, RADIO will have to retry the CCA after a specific back-off period. This is outlined in the *IEEE 802.15.4 standard*, Figure 69 in section 7.5.1.4 *The CSMA-CA algorithm*.

If the **CCAIDLE** event is generated, a write to the **TXEN** task register enters RADIO in TXRU state. The **READY** event will be generated when RADIO is in TXIDLE state and ready to transmit. With the **PACKETPTR** pointing to the length (PHR) field of the frame, the **START** task can be written. RADIO will send the four octet preamble sequence followed by the start of frame delimiter (**SFD** register). The first byte read from the Data RAM is the length field (PHR) followed by the transmission of the number of bytes indicated as the frame length. If the CRC module is configured it will run for PHR-2 octets. The last two octets will be substituted with the results from running the CRC. The necessary CRC parameters are sampled on the **START** task. The FCS field of the frame is little endian.

In addition to the already available shortcuts, one is provided between the **READY** event and the **CCASTART** task so that a CCA can automatically start when the receiver is ready. A second shortcut has been added between the **CCAIDLE** event and the **TXEN** task, so that upon detecting a clear channel RADIO can immediately enter TX mode.

### 7.26.13.7 Receive sequence

The reception is started by first putting RADIO in receive mode. After writing to the **RXEN** task, RADIO will start ramping up and enter the RXRU state.

When the **READY** event is generated, RADIO enters the RXIDLE mode. For the baseband processing to be enabled, the **START** task must be written. An outline of the IEEE 802.15.4 reception can be found in the following figure.

Figure 173: IEEE 802.15.4 receive sequence

When a valid SHR is received, RADIO will start storing future octets (starting with PHR) to the data memory pointed to by [PACKETPTR](#). After the SFD octet is received, the [FRAMESTART](#) event is generated. If the CRC module is enabled it will start updating with the second byte received (first byte in payload) and run for the full frame length. The two last bytes in the frame are not written to RAM when CRC is configured. However, if the result of the CRC after running the full frame is zero, the [CRCOK](#) event will be generated. The [END](#) event is generated when the last octet has been received and is available in data memory.

When a packet is received, a link quality indicator (LQI) is also generated and appended immediately after the last received octet. When using an IEEE 802.15.4 compliant frame, this will be just after the MSDU since the FCS is not reported. In the case of a non-compliant frame, it will be appended after the full frame. The LQI reported by the hardware must be converted to the IEEE 802.15.4 range by an 8-bit saturating multiplication of 4, as shown in [IEEE 802.15.4 ED measurement example](#) on page 509. The LQI is only valid for frames equal to or longer than three octets. When receiving a frame, the RSSI (reported as negative dB) will be measured at three points during the reception. These three values will be sorted and the middle one selected (median 3) to be remapped within the LQI range. The following figure illustrates the LQI measurement and how the data is arranged in data memory.

Figure 174: IEEE 802.15.4 frame in data memory

A shortcut has been added between the **FRAMESTART** event and the **BCSTART** task. This can be used to trigger a **BCMATCH** event after N bits, such as when inspecting the MAC addressing fields.

### 7.26.13.8 Interframe spacing (IFS)

The IEEE 802.15.4 standard defines a specific time that is allotted for the MAC sublayer to process received data. The interframe spacing (IFS) is used to prevent two frames from being transmitted too close together. If the transmission is requesting an acknowledgement, the space before the second frame shall be at least one IFS period.

IFS is determined to be one of the following:

- IFS equals `macMinSIFSPeriod` (12 symbols) if the MPDU is less than or equal to `aMaxSIFSFrameSize` (18 octets) octets
- IFS equals `macMinLIFSPeriod` (40 symbols) if the MPDU is larger than `aMaxSIFSFrameSize`

Using the efficient assisted modes in RADIO, the **TIFS** will be programmed with the correct value based on the frame being transmitted. If the assisted modes are not in use, the **TIFS** register must be updated manually. The following figure provides details on what IFS period is valid in both acknowledged and unacknowledged transmissions.

Figure 175: Interframe spacing examples

### 7.26.14 EasyDMA

RADIO uses EasyDMA to read and write packets to RAM without CPU involvement.

As illustrated in [RADIO block diagram](#) on page 493, RADIO's EasyDMA utilizes the same [PACKETPTR](#) for receiving and transmitting packets. This pointer should be reconfigured by the CPU each time before RADIO is started by the [START](#) task. The [PACKETPTR](#) register is double-buffered, meaning that it can be updated and prepared for the next transmission.

The [END](#) event indicates that the last bit has been processed by RADIO. The [DISABLED](#) event is issued to acknowledge that a [DISABLE](#) task is done.

The structure of a packet is described in detail in [Packet configuration](#) on page 493. The data that is stored in Data RAM and transported by EasyDMA consists of the following fields:

- S0
- LENGTH
- S1
- PAYLOAD

In addition, a static add-on is sent immediately after the payload.

The size of each of the above fields in the frame is configurable (see [Packet configuration](#) on page 493), and the space occupied in RAM depends on these settings. The size of the field can be zero, as long as the resulting frame complies with the chosen RF protocol.

All fields are extended in size to align with a byte boundary in RAM. For instance, a 3-bit long field on air will occupy 1 byte in RAM while a 9-bit long field will be extended to 2 bytes.

The packet's elements can be configured as follows:

- CI, TERM1, and TERM2 fields are only present in Bluetooth Low Energy Long Range mode
- S0 is configured through the [PCNF0.SOLEN](#) field
- LENGTH is configured through the [PCNF0.LFLEN](#) field
- S1 is configured through the [PCNF0.S1LEN](#) field
- Payload size is configured through the value in RAM corresponding to the LENGTH field
- Static add-on size is configured through the [PCNF1.STATLEN](#) field

The [PCNF1.MAXLEN](#) field configures the maximum packet payload plus add-on size in number of bytes that can be transmitted or received by RADIO. This feature can be used to ensure that RADIO does not overwrite, or read beyond, the RAM assigned to the packet payload. This means that if the LENGTH field of the packet payload exceeds [PCNF1.STATLEN](#), and the LENGTH field in the packet specifies a packet larger than configured in [PCNF1.MAXLEN](#), the payload will be truncated to the length specified in [PCNF1.MAXLEN](#).

**Note:** The `PCNF1.MAXLEN` field includes the payload and the add-on, but excludes the size occupied by the `S0`, `LENGTH`, and `S1` fields. This has to be taken into account when allocating RAM.

If the payload and add-on length is specified larger than `PCNF1.MAXLEN`, RADIO will still transmit or receive in the same way as before, except the payload is now truncated to `PCNF1.MAXLEN`. The packet's `LENGTH` field will not be altered when the payload is truncated. RADIO will calculate CRC as if the packet length is equal to `PCNF1.MAXLEN`.

**Note:** If `PACKETPTR` is not pointing to the Data RAM region, an EasyDMA transfer may result in a HardFault or RAM corruption. See [Memory](#) on page 21 for more information about the different memory regions.

The `END` event indicates that the last bit has been processed by RADIO. The `DISABLED` event is issued to acknowledge that an `DISABLE` task is done.

## 7.26.15 Registers

### Instances

| Instance | Domain  | Base address | TrustZone |     |     | Split access | Description   |
|----------|---------|--------------|-----------|-----|-----|--------------|---------------|
|          |         |              | Map       | Att | DMA |              |               |
| RADIO    | NETWORK | 0x41008000   | HF        | NS  | NA  | No           | 2.4 GHz radio |

### Register overview

| Register                         | Offset | TZ | Description                                                              |
|----------------------------------|--------|----|--------------------------------------------------------------------------|
| <code>TASKS_TXEN</code>          | 0x000  |    | Enable RADIO in TX mode                                                  |
| <code>TASKS_RXEN</code>          | 0x004  |    | Enable RADIO in RX mode                                                  |
| <code>TASKS_START</code>         | 0x008  |    | Start RADIO                                                              |
| <code>TASKS_STOP</code>          | 0x00C  |    | Stop RADIO                                                               |
| <code>TASKS_DISABLE</code>       | 0x010  |    | Disable RADIO                                                            |
| <code>TASKS_RSSISTART</code>     | 0x014  |    | Start the RSSI and take one single sample of the receive signal strength |
| <code>TASKS_RSSISTOP</code>      | 0x018  |    | Stop the RSSI measurement                                                |
| <code>TASKS_BCSTART</code>       | 0x01C  |    | Start the bit counter                                                    |
| <code>TASKS_BCSTOP</code>        | 0x020  |    | Stop the bit counter                                                     |
| <code>TASKS_EDSTART</code>       | 0x024  |    | Start the energy detect measurement used in IEEE 802.15.4 mode           |
| <code>TASKS_EDSTOP</code>        | 0x028  |    | Stop the energy detect measurement                                       |
| <code>TASKS_CCASTART</code>      | 0x02C  |    | Start the clear channel assessment used in IEEE 802.15.4 mode            |
| <code>TASKS_CCASSTOP</code>      | 0x030  |    | Stop the clear channel assessment                                        |
| <code>SUBSCRIBE_TXEN</code>      | 0x080  |    | Subscribe configuration for task <code>TXEN</code>                       |
| <code>SUBSCRIBE_RXEN</code>      | 0x084  |    | Subscribe configuration for task <code>RXEN</code>                       |
| <code>SUBSCRIBE_START</code>     | 0x088  |    | Subscribe configuration for task <code>START</code>                      |
| <code>SUBSCRIBE_STOP</code>      | 0x08C  |    | Subscribe configuration for task <code>STOP</code>                       |
| <code>SUBSCRIBE_DISABLE</code>   | 0x090  |    | Subscribe configuration for task <code>DISABLE</code>                    |
| <code>SUBSCRIBE_RSSISTART</code> | 0x094  |    | Subscribe configuration for task <code>RSSISTART</code>                  |
| <code>SUBSCRIBE_RSSISTOP</code>  | 0x098  |    | Subscribe configuration for task <code>RSSISTOP</code>                   |
| <code>SUBSCRIBE_BCSTART</code>   | 0x09C  |    | Subscribe configuration for task <code>BCSTART</code>                    |
| <code>SUBSCRIBE_BCSTOP</code>    | 0x0A0  |    | Subscribe configuration for task <code>BCSTOP</code>                     |
| <code>SUBSCRIBE_EDSTART</code>   | 0x0A4  |    | Subscribe configuration for task <code>EDSTART</code>                    |
| <code>SUBSCRIBE_EDSTOP</code>    | 0x0A8  |    | Subscribe configuration for task <code>EDSTOP</code>                     |
| <code>SUBSCRIBE_CCASTART</code>  | 0x0AC  |    | Subscribe configuration for task <code>CCASTART</code>                   |
| <code>SUBSCRIBE_CCASSTOP</code>  | 0x0B0  |    | Subscribe configuration for task <code>CCASSTOP</code>                   |

| Register           | Offset | TZ | Description                                                                                                   |
|--------------------|--------|----|---------------------------------------------------------------------------------------------------------------|
| EVENTS_READY       | 0x100  |    | RADIO has ramped up and is ready to be started                                                                |
| EVENTS_ADDRESS     | 0x104  |    | Address sent or received                                                                                      |
| EVENTS_PAYLOAD     | 0x108  |    | Packet payload sent or received                                                                               |
| EVENTS_END         | 0x10C  |    | Packet sent or received                                                                                       |
| EVENTS_DISABLED    | 0x110  |    | RADIO has been disabled                                                                                       |
| EVENTS_DEVMATCH    | 0x114  |    | A device address match occurred on the last received packet                                                   |
| EVENTS_DEVMISS     | 0x118  |    | No device address match occurred on the last received packet                                                  |
| EVENTS_RSSIEND     | 0x11C  |    | Sampling of receive signal strength complete                                                                  |
| EVENTS_BCMATCH     | 0x128  |    | Bit counter reached bit count value                                                                           |
| EVENTS_CRCOK       | 0x130  |    | Packet received with CRC ok                                                                                   |
| EVENTS_CRCERROR    | 0x134  |    | Packet received with CRC error                                                                                |
| EVENTS_FRAMESTART  | 0x138  |    | IEEE 802.15.4 length field received                                                                           |
| EVENTS_EDEND       | 0x13C  |    | Sampling of energy detection complete. A new ED sample is ready for readout from the RADIO.EDSAMPLE register. |
| EVENTS_EDSTOPPED   | 0x140  |    | The sampling of energy detection has stopped                                                                  |
| EVENTS_CCAIDLE     | 0x144  |    | Wireless medium in idle - clear to send                                                                       |
| EVENTS_CCABUSY     | 0x148  |    | Wireless medium busy - do not send                                                                            |
| EVENTS_CCASTOPPED  | 0x14C  |    | The CCA has stopped                                                                                           |
| EVENTS_RATEBOOST   | 0x150  |    | Ble_LR CI field received, receive mode is changed from Ble_LR125Kbit to Ble_LR500Kbit.                        |
| EVENTS_TXREADY     | 0x154  |    | RADIO has ramped up and is ready to be started TX path                                                        |
| EVENTS_RXREADY     | 0x158  |    | RADIO has ramped up and is ready to be started RX path                                                        |
| EVENTS_MHRMATCH    | 0x15C  |    | MAC header match found                                                                                        |
| EVENTS_SYNC        | 0x168  |    | Preamble indicator                                                                                            |
| EVENTS_PHYEND      | 0x16C  |    | Generated when last bit is sent on air, or received from air                                                  |

### 7.26.15.48 EVENTS\_SYNC

Address offset: 0x168

Preamble indicator

A possible preamble has been received in Ble\_LR125Kbit, Ble\_LR500Kbit, or leee802154\_250Kbit modes during an RX transaction. False triggering of the event is possible.

 When transmitting, the packet pointed to by this address will be transmitted and when receiving, the received packet will be written to this address. This address is a byte aligned RAM address. See the memory chapter for details about which memories are available for EasyDMA. |                |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

 |-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|---------|----------|-------|----------------|
| A                                                                                                                                                                                                                                                                                                                                                         | RW  | CRCPOLY |          |       | CRC polynomial |
| Each term in the CRC polynomial is mapped to a bit in this register which index corresponds to the term's exponent. The least significant term/bit is hardwired internally to 1, and bit number 0 of the register content is ignored by the hardware. The following example is for an 8 bit CRC polynomial: $x^8 + x^7 + x^3 + x^2 + 1 = 1\ 1000\ 1101$ . |     |         |          |       |                |

 ### 7.26.15.112 EDCNT

Address offset: 0x664

IEEE 802.15.4 energy detect loop count

Number of iterations to perform an ED scan. If set to 0 one scan is performed, otherwise the specified number + 1 of ED scans will be performed and the max ED value tracked in EDSAMPLE.

### 7.26.15.119 SWITCHPATTERN

Address offset: 0x928

GPIO patterns to be used for each antenna

Maximum 8 GPIOs can be controlled. To secure correct signal levels on the pins, the pins must be configured in the GPIO peripheral as described in Pin configuration.

If, during switching, the total number of antenna slots is bigger than the number of written patterns, the RADIO loops back to the pattern used after the reference pattern.

A minimum number of three patterns must be written.

|                  |     |               |          |                                                                                       |                                                                                                                                                                                                                                                                                                                                                                     |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

## 7.26.16 Electrical specification

### 7.26.16.1 General radio characteristics

| Symbol                    | Description                               | Min. | Typ. | Max. | Units   |
|---------------------------|-------------------------------------------|------|------|------|---------|
| $f_{OP}$                  | Operating frequencies                     | 2360 |      | 2500 | MHz     |
| $f_{PLL,CH,SP}$           | PLL channel spacing                       |      | 1.0  |      | MHz     |
| $f_{DELTA,1M}$            | Frequency deviation @ 1 Mbps              |      | ±170 |      | kHz     |
| $f_{DELTA,BLE,1M}$        | Frequency deviation @ Bluetooth LE 1 Mbps |      | ±250 |      | kHz     |
| $f_{DELTA,2M}$            | Frequency deviation @ 2 Mbps              |      | ±320 |      | kHz     |
| $f_{DELTA,BLE,2M}$        | Frequency deviation @ Bluetooth LE 2 Mbps |      | ±500 |      | kHz     |
| $f_{skBPS}$               | On-the-air data rate                      | 125  |      | 2000 | kbps    |
| $f_{chip, IEEE 802.15.4}$ | Chip rate in IEEE 802.15.4 mode           |      | 2000 |      | kchip/s |

### 7.26.16.2 Radio current consumption (transmitter)

| Symbol                   | Description                                        | Min. | Typ. | Max. | Units |
|--------------------------|----------------------------------------------------|------|------|------|-------|
| $I_{TX,PLUS3dBm,DCDC}$   | TX only run current DC/DC, 3 V, $P_{RF} = +3$ dBm  |      | 5.1  |      | mA    |
| $I_{TX,PLUS3dBm}$        | TX only run current $P_{RF} = +3$ dBm              |      | 11.3 |      | mA    |
| $I_{TX,0dBm,DCDC}$       | TX only run current DC/DC, 3 V, $P_{RF} = 0$ dBm   |      | 3.4  |      | mA    |
| $I_{TX,0dBm}$            | TX only run current $P_{RF} = 0$ dBm               |      | 9.1  |      | mA    |
| $I_{TX,MINUS4dBm,DCDC}$  | TX only run current DC/DC, 3 V, $P_{RF} = -4$ dBm  |      | 2.7  |      | mA    |
| $I_{TX,MINUS4dBm}$       | TX only run current $P_{RF} = -4$ dBm              |      | 7.2  |      | mA    |
| $I_{TX,MINUS8dBm,DCDC}$  | TX only run current DC/DC, 3 V, $P_{RF} = -8$ dBm  |      | 2.2  |      | mA    |
| $I_{TX,MINUS8dBm}$       | TX only run current $P_{RF} = -8$ dBm              |      | 5.8  |      | mA    |
| $I_{TX,MINUS12dBm,DCDC}$ | TX only run current DC/DC, 3 V, $P_{RF} = -12$ dBm |      | 2.0  |      | mA    |
| $I_{TX,MINUS12dBm}$      | TX only run current $P_{RF} = -12$ dBm             |      | 5.0  |      | mA    |
| $I_{TX,MINUS16dBm,DCDC}$ | TX only run current DC/DC, 3 V, $P_{RF} = -16$ dBm |      | 1.8  |      | mA    |
| $I_{TX,MINUS16dBm}$      | TX only run current $P_{RF} = -16$ dBm             |      | 4.5  |      | mA    |
| $I_{TX,MINUS20dBm,DCDC}$ | TX only run current DC/DC, 3 V, $P_{RF} = -20$ dBm |      | 1.7  |      | mA    |
| $I_{TX,MINUS20dBm}$      | TX only run current $P_{RF} = -20$ dBm             |      | 4.2  |      | mA    |
| $I_{TX,MINUS40dBm,DCDC}$ | TX only run current DC/DC, 3 V, $P_{RF} = -40$ dBm |      | 1.5  |      | mA    |
| $I_{TX,MINUS40dBm}$      | TX only run current $P_{RF} = -40$ dBm             |      | 3.8  |      | mA    |
| $I_{START,TX,DCDC}$      | TX start-up current DC/DC, 3 V, $P_{RF} = 3$ dBm   |      | 2.4  |      | mA    |
| $I_{START,TX}$           | TX start-up current, $P_{RF} = 3$ dBm              |      | 5.4  |      | mA    |

### 7.26.16.3 Radio current consumption (receiver)

| Symbol                 | Description                                                     | Min. | Typ. | Max. | Units |
|------------------------|-----------------------------------------------------------------|------|------|------|-------|
| $I_{RX,1M,DCDC}$       | RX only run current DC/DC, 3 V, 1 Mbps/1 Mbps Bluetooth LE mode |      | 2.7  |      | mA    |
| $I_{RX,1M}$            | RX only run current LDO, 3 V, 1 Mbps/1 Mbps Bluetooth LE mode   |      | 6.7  |      | mA    |
| $I_{RX,2M,DCDC}$       | RX only run current DC/DC, 3 V, 2 Mbps/2 Mbps Bluetooth LE mode |      | 3.1  |      | mA    |
| $I_{RX,2M}$            | RX only run current LDO, 3 V, 2 Mbps/2 Mbps Bluetooth LE mode   |      | 7.9  |      | mA    |
| $I_{START,RX,1M,DCDC}$ | RX start-up current DC/DC, 3 V, 1 Mbps/1 Mbps Bluetooth LE mode |      | 2.1  |      | mA    |
| $I_{START,RX,1M}$      | RX start-up current 1 Mbps/1 Mbps Bluetooth LE mode             |      | 5.3  |      | mA    |

### 7.26.16.4 Transmitter specification

| Symbol    | Description            | Min. | Typ. | Max. | Units |
|-----------|------------------------|------|------|------|-------|
| $P_{RF}$  | Maximum output power   |      | 3.0  |      | dBm   |
| $P_{RFC}$ | RF power control range |      | 23.0 |      | dB    |

| Symbol                               | Description                                                                   | Min. | Typ.              | Max. | Units |
|--------------------------------------|-------------------------------------------------------------------------------|------|-------------------|------|-------|
| P <sub>RF,CR</sub>                   | RF power accuracy                                                             |      | ±2                |      | dB    |
| P <sub>RF1,1</sub>                   | 1st Adjacent Channel Transmit Power 1 MHz (1 Mbps)                            |      | -24 <sup>13</sup> |      | dBc   |
| P <sub>RF2,1</sub>                   | 2nd Adjacent Channel Transmit Power 2 MHz (1 Mbps)                            |      | -52 <sup>13</sup> |      | dBc   |
| P <sub>RF1,2</sub>                   | 1st Adjacent Channel Transmit Power 2 MHz (2 Mbps)                            |      | -25 <sup>14</sup> |      | dBc   |
| P <sub>RF2,2</sub>                   | 2nd Adjacent Channel Transmit Power 4 MHz (2 Mbps)                            |      | -50 <sup>14</sup> |      | dBc   |
| E <sub>vm</sub>                      | Error vector magnitude in IEEE 802.15.4 mode                                  |      | 9                 |      | %rms  |
| P <sub>harm2nd</sub> , IEEE 802.15.4 | 2nd harmonics in IEEE 802.15.4 mode                                           |      | -51               |      | dBm   |
| P <sub>harm3rd</sub> , IEEE 802.15.4 | 3rd harmonics in IEEE 802.15.4 mode                                           |      | -51               |      | dBm   |
| P <sub>ACP,R</sub> , IEEE 802.15.4   | IEEE 802.15.4 Relative adjacent Channel Power, offset > 3.5 MHz <sup>15</sup> |      | -36               |      | dBc   |
| P <sub>ACP,A</sub> , IEEE 802.15.4   | IEEE 802.15.4 Absolute adjacent Channel Power, offset > 3.5 MHz <sup>15</sup> |      | -36               |      | dBm   |

Figure 176: Output power, 1 Mbps Bluetooth low energy mode, at maximum TXPOWER setting (typical values)

<sup>13</sup> MODE = Nrf\_1Mbit

<sup>14</sup> MODE = Nrf\_2Mbit

<sup>15</sup> Output power set to maximum TXPOWER setting, resolution bandwidth (RBW) set to 100 kHz, and transmitter Duty-Cycle approximately 85%.

Figure 177: Output power, 1 Mbps Bluetooth low energy mode, at 0 dBm TXPOWER setting (typical values)

### 7.26.16.5 Receiver operation

| Symbol                          | Description                                                                                               | Min. | Typ. | Max. | Units |
|---------------------------------|-----------------------------------------------------------------------------------------------------------|------|------|------|-------|
| P <sub>RX,MAX</sub>             | Maximum received signal strength at < 0.1% PER                                                            |      | 0    |      | dBm   |
| P <sub>SENS,IT,1M</sub>         | Sensitivity, 1 Mbps nRF mode ideal transmitter <sup>16</sup>                                              |      | -95  |      | dBm   |
| P <sub>SENS,IT,2M</sub>         | Sensitivity, 2 Mbps nRF mode ideal transmitter <sup>16</sup>                                              |      | -92  |      | dBm   |
| P <sub>SENS,IT,SP,1M,BLE</sub>  | Sensitivity, 1 Mbps Bluetooth LE ideal transmitter, packet length ≤ 37 bytes<br>BER = 1E-3 <sup>17</sup>  |      | -98  |      | dBm   |
| P <sub>SENS,IT,LP,1M,BLE</sub>  | Sensitivity, 1 Mbps Bluetooth LE ideal transmitter, packet length ≥ 128 bytes<br>BER = 1E-4 <sup>18</sup> |      | -97  |      | dBm   |
| P <sub>SENS,IT,SP,2M,BLE</sub>  | Sensitivity, 2 Mbps Bluetooth LE ideal transmitter, packet length ≤ 37 bytes                              |      | -95  |      | dBm   |
| P <sub>SENS,IT,BLE LE125k</sub> | Sensitivity, 125 kbps Bluetooth LE mode                                                                   |      | -104 |      | dBm   |
| P <sub>SENS,IT,BLE LE500k</sub> | Sensitivity, 500 kbps Bluetooth LE mode                                                                   |      | -100 |      | dBm   |
| P <sub>SENS,IEEE 802.15.4</sub> | Sensitivity in IEEE 802.15.4 mode                                                                         |      | -101 |      | dBm   |

<sup>16</sup> Typical sensitivity applies when ADDR0 is used for receiver address correlation. When ADDR[1...7] are used for receiver address correlation, the typical sensitivity for this mode is degraded by 3 dB.

<sup>17</sup> As defined in the *Bluetooth Core Specification v4.0 Volume 6: Core System Package (Low Energy Controller Volume)*.

<sup>18</sup> Equivalent BER limit < 10E-04.

Figure 178: Sensitivity, 1 Mbps Bluetooth low energy mode, Regulator = DCDC (typical values)

## 7.26.16.6 Receiver selectivity

Receiver selectivity with equal modulation on interfering signal<sup>19</sup>

| Symbol                          | Description                                              | Min. | Typ. | Max. | Units |
|---------------------------------|----------------------------------------------------------|------|------|------|-------|
| C/I <sub>1M,co-channel</sub>    | 1Mbps mode, co-channel interference                      | ..   | ..   | ..   | dB    |
| C/I <sub>1M,-1MHz</sub>         | 1 Mbps mode, Adjacent (-1 MHz) interference              | ..   | ..   | ..   | dB    |
| C/I <sub>1M,+1MHz</sub>         | 1 Mbps mode, Adjacent (+1 MHz) interference              | ..   | ..   | ..   | dB    |
| C/I <sub>1M,-2MHz</sub>         | 1 Mbps mode, Adjacent (-2 MHz) interference              | ..   | ..   | ..   | dB    |
| C/I <sub>1M,+2MHz</sub>         | 1 Mbps mode, Adjacent (+2 MHz) interference              | ..   | ..   | ..   | dB    |
| C/I <sub>1M,-3MHz</sub>         | 1 Mbps mode, Adjacent (-3 MHz) interference              | ..   | ..   | ..   | dB    |
| C/I <sub>1M,+3MHz</sub>         | 1 Mbps mode, Adjacent (+3 MHz) interference              | ..   | ..   | ..   | dB    |
| C/I <sub>1M,±6MHz</sub>         | 1 Mbps mode, Adjacent (≥6 MHz) interference              | ..   | ..   | ..   | dB    |
| C/I <sub>1MBLE,co-channel</sub> | 1 Mbps Bluetooth LE mode, co-channel interference        |      | 6.9  |      | dB    |
| C/I <sub>1MBLE,-1MHz</sub>      | 1 Mbps Bluetooth LE mode, Adjacent (-1 MHz) interference |      | -2.6 |      | dB    |
| C/I <sub>1MBLE,+1MHz</sub>      | 1 Mbps Bluetooth LE mode, Adjacent (+1 MHz) interference |      | -8.5 |      | dB    |
| C/I <sub>1MBLE,-2MHz</sub>      | 1 Mbps Bluetooth LE mode, Adjacent (-2 MHz) interference |      | -27  |      | dB    |
| C/I <sub>1MBLE,+2MHz</sub>      | 1 Mbps Bluetooth LE mode, Adjacent (+2 MHz) interference |      | -45  |      | dB    |
| C/I <sub>1MBLE,&gt;3MHz</sub>   | 1 Mbps Bluetooth LE mode, Adjacent (≥3 MHz) interference |      | -50  |      | dB    |
| C/I <sub>1MBLE,image</sub>      | Image frequency interference                             |      | -27  |      | dB    |
| C/I <sub>1MBLE,image,1MHz</sub> | Adjacent (1 MHz) interference to in-band image frequency |      | -41  |      | dB    |
| C/I <sub>2M,co-channel</sub>    | 2 Mbps mode, co-channel interference                     | ..   | ..   | ..   | dB    |
| C/I <sub>2M,-2MHz</sub>         | 2 Mbps mode, Adjacent (-2 MHz) interference              | ..   | ..   | ..   | dB    |

### 7.26.16.7 Receiver intermodulation

Receiver intermodulation. Desired signal level at P<sub>IN</sub> = -64 dBm. Two interferers with equal input power are used. The interferer closest in frequency is not modulated, the other interferer is modulated equal with the desired signal. The input power of the interferers where the sensitivity equals BER = 1E-3 is presented.

| Symbol                      | Description                                                                        | Min. | Typ. | Max. | Units |
|-----------------------------|------------------------------------------------------------------------------------|------|------|------|-------|

### 7.26.16.9 Received signal strength indicator (RSSI) specifications

| Symbol                            | Description                                  | Min. | Typ.    | Max. | Units         |
|-----------------------------------|----------------------------------------------|------|---------|------|---------------|
| $\text{RSSI}_{\text{ACC}}$        | RSSI accuracy                                |      | $\pm 2$ |      | dB            |
| $\text{RSSI}_{\text{RESOLUTION}}$ | RSSI resolution                              |      | 1       |      | dB            |
| $\text{RSSI}_{\text{PERIOD}}$     | RSSI sampling time from RSSI_START task      |      | 0.25    |      | $\mu\text{s}$ |
| $\text{RSSI}_{\text{SETTLE}}$     | RSSI settling time after signal level change |      | 15      |      | $\mu\text{s}$ |

### 7.26.16.10 Jitter

| Symbol                      | Description                                                                                     | Min. | Typ. | Max. | Units         |
|-----------------------------|-------------------------------------------------------------------------------------------------|------|------|------|---------------|
| $t_{\text{DISABLEDJITTER}}$ | Jitter on DISABLED event relative to END event when shortcut between END and DISABLE is enabled |      | 0.25 |      | $\mu\text{s}$ |
| $t_{\text{READYJITTER}}$    | Jitter on READY event relative to TXEN and RXEN task                                            |      | 0.25 |      | $\mu\text{s}$ |

### 7.26.16.11 IEEE 802.15.4 mode energy detection constants

| Symbol                 | Description                                                           | Min. | Typ. | Max. | Units |
|------------------------|-----------------------------------------------------------------------|------|------|------|-------|
| $\text{ED\_RSSISCALE}$ | Scaling value when converting between hardware-reported value and dBm |      | 4    |      |       |
| $\text{ED\_RSSIOFFS}$  | Offset value when converting between hardware-reported value and dBm  |      | -93  |      |       |

## 7.27 RNG — Random number generator

The Random number generator (RNG) generates true non-deterministic random numbers based on internal thermal noise that are suitable for cryptographic purposes. The RNG does not require a seed value.

Figure 179: Random number generator

The RNG is started by triggering the START task and stopped by triggering the STOP task. When started, new random numbers are generated continuously and written to the VALUE register when ready. A VALRDY event is generated for every new random number that is written to the VALUE register. This means that after a VALRDY event is generated, the CPU has the time until the next VALRDY event to read out the random number from the VALUE register before it is overwritten by a new random number.

### 7.27.1 Bias correction

A bias correction algorithm is employed on the internal bit stream to remove any bias toward 1 or 0. The bits are then queued into an eight-bit register for parallel readout from the VALUE register.

It is possible to enable bias correction in the CONFIG register. This will result in slower value generation, but will ensure a statistically uniform distribution of the random values.

### 7.27.2 Speed

The time needed to generate one random byte of data is unpredictable, and may vary from one byte to the next. This is especially true when bias correction is enabled.

### 7.27.3 Registers

#### Instances

| Instance | Domain  | Base address | TrustZone |     |     | Split access | Description             |
|----------|---------|--------------|-----------|-----|-----|--------------|-------------------------|

 ## 7.27.4 Electrical specification

### 7.27.4.1 RNG Electrical Specification

| Symbol                 | Description                                                                                                                          | Min. | Typ. | Max. | Units |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------|------|------|------|-------|
| t <sub>RNG,START</sub> | Time from setting the START task to generation begins. This is a one-time delay on START signal and does not apply between samples.  |      | 128  |      | μs    |
| t <sub>RNG,RAW</sub>   | Run time per byte without bias correction. Uniform distribution of 0 and 1 is not guaranteed.                                        |      | 32   |      | μs    |
| t <sub>RNG,BC</sub>    | Run time per byte with bias correction. Uniform distribution of 0 and 1 is guaranteed. Time to generate a byte cannot be guaranteed. |      |      | 122  | μs    |

## 7.28 RTC — Real-time counter

The real-time counter (RTC) module provides a generic, low-power timer on the low frequency clock source (LFCLK).

Figure 180: RTC block diagram

The RTC module features a 24-bit COUNTER, a 12-bit (1/X) prescaler, capture/compare registers, and a tick event generator.

### 7.28.1 Clock source

The RTC will run off the LFCLK.

When started, the RTC will automatically request the LFCLK source with RC oscillator if the LFCLK is not already running.

See [CLOCK — Clock control](#) on page 72 for more information about clock sources.

### 7.28.2 Resolution versus overflow and the prescaler

The relationship between the prescaler, counter resolution, and overflow is summarized in the following table.

| Prescaler  | Counter resolution | Overflow       |
|------------|--------------------|----------------|
| 0          | 30.517 $\mu$ s     | 512 seconds    |
| $2^8-1$    | 7812.5 $\mu$ s     | 131072 seconds |
| $2^{12}-1$ | 125 ms             | 582.542 hours  |

Table 59: RTC resolution versus overflow

The counter increment frequency is given by the following equation:

$$f_{\text{RTC}} [\text{kHz}] = 32.768 / (\text{PRESCALER} + 1)$$

The **PRESCALER** register can only be written when the RTC is stopped.

The prescaler is restarted on tasks **START**, **CLEAR** and **TRIGOVRFW**. That is, the prescaler value is latched to an internal register (<<PRESC>>) on these tasks.

Examples:

1. Desired COUNTER frequency 100 Hz (10 ms counter period)

$$\text{PRESCALER} = \text{round}(32.768 \text{ kHz} / 100 \text{ Hz}) - 1 = 327$$

$$f_{\text{RTC}} = 99.9 \text{ Hz}$$

$$10009.576 \text{ } \mu\text{s} \text{ counter period}$$

2. Desired COUNTER frequency 8 Hz (125 ms counter period)

$$\text{PRESCALER} = \text{round}(32.768 \text{ kHz} / 8 \text{ Hz}) - 1 = 4095$$

$$f_{\text{RTC}} = 8 \text{ Hz}$$

$$125 \text{ ms counter period}$$

### 7.28.3 Counter register

The internal <<COUNTER>> register increments on LFCLK when the internal PRESCALER register (<<PRESC>>) is 0x00. <<PRESC>> is reloaded from the PRESCALER register. If enabled, the TICK event occurs on each increment of the COUNTER.

Figure 181: Timing diagram - COUNTER\_PRESCALER\_0

Figure 182: Timing diagram - COUNTER\_PRESCALER\_1

#### 7.28.3.1 Reading the counter register

To read the COUNTER register, the internal <<COUNTER>> value is sampled.

To ensure that the <<COUNTER>> is safely sampled (considering that an LFCLK transition may occur during a read), the CPU and core memory bus are halted for four PCLK16M cycles. In addition, the read takes the CPU two PCLK16M cycles, resulting in the COUNTER register read taking maximum six PCLK16M clock cycles.

### 7.28.4 Overflow

An OVRFLW event is generated on COUNTER register overflow (overflowing from 0xFFFFFFFF to 0).

The **TRIGOVFLW** task will set the **COUNTER** value to `0xFFFFF0`, to allow software test of the overflow condition.

**Note:** The **OVRFLW** event is disabled by default.

### 7.28.5 Tick event

The **TICK** event enables low-power tickless RTOS implementation, as it optionally provides a regular interrupt source for an RTOS with no need for use of the ARM SysTick feature.

Using the **TICK** event, rather than the SysTick, allows the CPU to be powered down while keeping RTOS scheduling active.

**Note:** The **TICK** event is disabled by default.

### 7.28.6 Event control

To optimize the RTC power consumption, events in the RTC can be individually disabled to prevent PCLK16M and HFCLK from being requested when those events are triggered. This is managed using the **EVTEN** register.

This means that the RTC implements a slightly different task and event system compared to the standard system described in [Peripheral interface](#) on page 149. The RTC task and event system is illustrated in the following figure.

Figure 183: Tasks, events, and interrupts in the RTC

### 7.28.7 Capture

The RTC implements one capture task for every available capture/compare register.

Every time `TASKS_CAPTURE[n]` is triggered, `<<COUNTER>>` is copied to the corresponding `CC[n]` register.

If the `CAPTURE` and `CLEAR` tasks are triggered at the same time, the `CAPTURE` task will be prioritized. This means that the `CC[n]` register for the corresponding `CAPTURE[n]` task will be set to the captured value before the counter is reset. There is a delay of 6 `PCLK16M` periods from when the `TASKS_CAPTURE[n]` is triggered until the corresponding `CC[n]` register is updated.

The `CAPTURE[n]` tasks will not generate `COMPARE[n]` events, even though `CC[n]` will then equal the `COUNTER`.

### 7.28.8 Compare

The RTC implements one `COMPARE` event for every available compare register.

When the `COUNTER` is incremented and then becomes equal to the value specified in the register `CC[n]`, the corresponding compare event `COMPARE[n]` is generated.

When writing a `CC[n]` register, the `RTC COMPARE` event exhibits several behaviors. See the following figures for more information.

If a `CC` value is 0 when a `CLEAR` task is set, this will not trigger a `COMPARE` event.

Figure 184: Timing diagram - `COMPARE_CLEAR`

If a `CC` value is `N` and the `COUNTER` value is `N` when the `START` task is set, this will not trigger a `COMPARE` event.

Figure 185: Timing diagram - `COMPARE_START`

A `COMPARE` event occurs when a `CC` value is `N`, and the `COUNTER` value transitions from `N-1` to `N`.

Figure 186: Timing diagram - COMPARE

If the **COUNTER** value is N, writing N+2 to a **CC** register is guaranteed to trigger a **COMPARE** event at N+2.

Figure 187: Timing diagram - COMPARE\_N+2

If the **COUNTER** value is N, writing N or N+1 to a **CC** register may not trigger a **COMPARE** event.

Figure 188: Timing diagram - COMPARE\_N+1

If the **COUNTER** value is N, and the current **CC** value is N+1 or N+2 when a new CC value is written, a match may trigger on the previous CC value before the new value takes effect. If the current CC value is greater than N+2 when the new value is written, there will be no event due to the old value.

Figure 189: Timing diagram - COMPARE\_N-1

If the COMPARE[i]\_CLEAR short is enabled, the **COUNTER** will be cleared one LFCLK after the **COMPARE** event.

Figure 190: Timing diagram - COMPARE\_CLEAR

### 7.28.9 Task and event jitter/delay

Jitter or delay in the RTC, is due to the peripheral clock being a low frequency clock (LFCLK), which is not synchronous to the faster PCLK16M.

Registers in the peripheral interface that are part of the PCLK16M domain, have a set of mirrored registers in the LFCLK domain. For example, the **COUNTER** value accessible from the CPU is in the PCLK16M domain, and is latched on a read from an internal COUNTER register in the LFCLK domain. The **COUNTER** register is modified each time the RTC ticks. The registers are synchronised between the two clock domains (PCLK16M and LFCLK).

**CLEAR** and **STOP** (and **TRIGOVFLW**, which is not shown) will be delayed as long as it takes for the peripheral to clock a falling edge and a rising edge of the LFCLK. This is between 15.2585  $\mu$ s and 45.7755  $\mu$ s – rounded to 15  $\mu$ s and 46  $\mu$ s for the remainder of the section.

Figure 191: Timing diagram - DELAY\_CLEAR

When a **STOP** task is triggered, the **PCLK16M** domain will immediately prevent the generation of any **EVENTS** from the RTC. However, as seen in the following figure, the **COUNTER** value can still increment one final time.

Figure 192: Timing diagram - DELAY\_STOP

The **START** task will start the RTC. Assuming that the **LFCLK** was previously running and stable, the first increment of **COUNTER** (and instance of **TICK** event) will be typically after  $30.5 \mu\text{s} \pm 15 \mu\text{s}$ . Additional delay will occur if the RTC is started before the **LFCLK** is running, see **CLOCK — Clock control** on page 72 for **LFLK** startup times. The software should therefore wait for the first **TICK** if it has to make sure that the RTC is running. Sending a **TRIGOVFLW** task sets the **COUNTER** to a value close to overflow. However, since the update of **COUNTER** relies on a stable **LFCLK**, sending this task while **LFCLK** is not running will also add additional delay as previously described. The figures show the smallest and largest delays on the **START** task, appearing as a  $\pm 15 \mu\text{s}$  jitter on the first **COUNTER** increment.

Figure 193: Timing diagram - JITTER\_START-

Figure 194: Timing diagram - JITTER\_START+

The following tables summarize jitter introduced for tasks and events. Any 32.768 kHz clock jitter will come in addition to these numbers.

| Task                            | Delay             |
|---------------------------------|-------------------|
| CLEAR, START, STOP, TRIGOVRFLOW | +15 to 46 $\mu$ s |

Table 60: RTC jitter magnitudes on tasks

| Operation/Function               | Jitter         |
|----------------------------------|----------------|
| START to COUNTER increment       | $\pm 15 \mu$ s |
| COMPARE to COMPARE <sup>20</sup> | $\pm 62.5$ ns  |

Table 61: RTC jitter magnitudes on events

## 7.28.10 Registers

### Instances

| Instance  | Domain      | Base address | TrustZone |     |     | Split access | Description         |

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

 ## 7.29 SAADC — Successive approximation analog-to-digital converter

SAADC is a differential successive approximation register (SAR) analog-to-digital converter (ADC).

The main features of SAADC are the following:

- 8/10/12-bit resolution, 14-bit resolution with oversampling
- Multiple analog inputs:

- **AIN0** to **AIN7** pins
- **VDD** pin
- **VDDHDIV5** (through **VDDH** pin)
- Up to eight input channels:
  - One channel per single-ended input and two channels per differential input
  - Scan mode can be configured with both single-ended channels and differential channels
  - Each channel can be configured to select any of the above analog inputs
- Full scale input range (0 to VDD)
- Sampling triggered via a task from software or a PPI channel for full flexibility on sample frequency source from a low-power 32.768 kHz RTC or more accurate 1/16 MHz timers
- One-shot conversion mode to sample a single channel
- Scan mode to sample a series of channels in sequence with configurable sample delay
- Support for direct sample transfer to RAM using EasyDMA
- Interrupts on single sample and full buffer events
- Samples stored as 16-bit two's complement values for differential and single-ended sampling
- Continuous sampling without the need of an external timer
- Internal resistor string
- On-the-fly limit checking

### 7.29.1 Shared resources

The ADC can coexist with COMP and other peripherals using one of **AIN0-AIN7**, provided these are assigned to different pins.

It is not recommended to select the same analog input pin for both modules.

### 7.29.2 Overview

The ADC supports up to eight external analog input channels. It can be operated in One-shot mode with sampling under software control, or Continuous mode with a programmable sampling rate.

The analog inputs can be configured as eight single-ended inputs, four differential inputs, or a combination of these. Each channel can be configured to select one of the following:

- **AIN0** to **AIN7** pins
- **VDD** pin
- **VDDHDIV5** (through **VDDH** pin)

Channels can be sampled individually in One-shot or Continuous sampling modes. Using Scan mode, multiple channels can be sampled in sequence. Channels can also be oversampled to improve noise performance.

Figure 195: Simplified ADC block diagram

Internally, the ADC is always a differential analog-to-digital converter, but by default it is configured with single-ended input `SE` in the `MODE` field of the `CH[n].CONFIG` register. In Single-ended (`SE`) mode, the negative input will be shorted to ground internally.

In Single-ended mode, the assumption is that the internal ground of the ADC is the same as the external ground that the measured voltage is referred to. The ADC is thus sensitive to ground bounce on the PCB. This can be reduced by configuring SAADC to use differential measurement setting the `MODE` field of the `CH[n].CONFIG` register to `Diff` (differential).

### 7.29.3 Digital output

The output result of the ADC depends on the settings in the `CH[n].CONFIG` and `RESOLUTION` registers as shown in the following equation.

$$\text{RESULT} = [V(P) - V(N)] * \text{GAIN}/\text{REFERENCE} * 2^{(\text{RESOLUTION} - m)}$$

| Variable               | Description                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>V(P)</code>      | Voltage at input P                                                                                                         |
| <code>V(N)</code>      | Voltage at input N                                                                                                         |
| <code>GAIN</code>      | Selected gain setting                                                                                                      |
| <code>m</code>         | Mode setting (Use <code>m=0</code> if <code>CONFIG.MODE=SE</code> , or <code>m=1</code> if <code>CONFIG.MODE=Diff</code> ) |
| <code>REFERENCE</code> | Selected reference voltage                                                                                                 |

Table 62: Equation variables

The result generated by the ADC will deviate from the expected due to DC errors like offset, gain, differential non-linearity (DNL), and integral non-linearity (INL). See [Electrical specification](#) for details on these parameters. The result can also vary due to AC errors like non-linearities in the `GAIN` block, settling errors due to high source impedance and sampling jitter. For battery measurement, the DC errors are most noticeable.

The ADC has a wide selection of gains controlled in the GAIN field of the CH[n].CONFIG register. If CH[n].CONFIG.REFSEL=0, the input range of the ADC core is nominally  $\pm 0.6$  V differential, and the input must be scaled accordingly.

The ADC has a temperature dependent offset. If the ADC is to operate over a large temperature range, it is recommended to run CALIBRATEOFFSET at regular intervals. The CALIBRATEDONE, DONE, and RESULTDONE events will be generated when the calibration has completed.

### 7.29.4 Analog inputs and channels

Up to eight analog input channels, CH[n](n=0..7), can be configured.

See [Shared resources](#) on page 588 for shared input with comparators.

Any of the available channels can be enabled for the ADC to operate in One-shot mode. If more than one CH[n] is configured, the ADC enters Scan mode.

An analog input is selected as a positive converter input if CH[n].PSELP is set, setting CH[n].PSELP also enables the particular channel.

An analog input is selected as a negative converter input if CH[n].PSELN is set. The CH[n].PSELN register will have no effect unless Differential mode is enabled, see MODE field in the CH[n].CONFIG register.

If more than one of the CH[n].PSELP registers is set, the device enters Scan mode. Input selections in Scan mode are controlled by the CH[n].PSELP and CH[n].PSELN registers, where CH[n].PSELN is only used if the particular scan channel is specified as differential, see MODE field in the CH[n].CONFIG register.

**Note:** Channels selected for COMP cannot be used at the same time for ADC sampling, though channels not selected for use by these blocks can be used by the ADC.

### 7.29.5 Operation modes

The ADC input configuration supports One-shot mode, Continuous mode, and Scan mode.

The ADC indicates a single ongoing conversion via the register [STATUS](#) on page 609. During Scan mode, oversampling, or Continuous modes, more than a single conversion take place in the ADC. As a consequence, the value reflected in the STATUS register will toggle at the end of each single conversion.

**Note:** Scan mode and oversampling cannot be combined.

#### 7.29.5.1 One-shot mode

One-shot operation is configured by enabling only one of the available channels defined by the CH[n].PSELP, CH[n].PSELN, and CH[n].CONFIG registers.

Once a SAMPLE task is triggered, the ADC starts to sample the input voltage. The CH[n].CONFIG.TACQ controls the acquisition time.

A DONE event signals that one sample has been taken.

In this mode, the RESULTDONE event has the same meaning as DONE when no oversampling takes place. Both events may occur before the actual value has been transferred into RAM by EasyDMA. For more information, see [EasyDMA](#) on page 592.

#### 7.29.5.2 Continuous mode

Continuous sampling can be achieved by using the internal timer in the ADC, or triggering the SAMPLE task from one of the general purpose timers through the PPI system.

Care shall be taken to ensure that the sample rate fulfills the following criteria, depending on how many channels are active.

$$f_{\text{SAMPLE}} < 1 / (t_{\text{ACQ}} + t_{\text{CONV}})$$

The SAMPLERATE register can be used as a local timer instead of triggering individual SAMPLE tasks. When SAMPLERATE.MODE is set to Timers, it is sufficient to trigger SAMPLE task only once in order to start the SAADC and triggering the STOP task will stop sampling. The SAMPLERATE.CC field controls the sample rate.

The SAMPLERATE timer mode cannot be combined with Scan mode, and only one channel can be enabled in this mode.

A DONE event signals that one sample has been taken.

In this mode, the RESULTDONE event has the same meaning as DONE when no oversampling takes place. Both events may occur before the actual value has been transferred into RAM by EasyDMA.

### 7.29.5.3 Oversampling

An accumulator in the ADC can be used to average noise on the analog input. In general, oversampling improves the signal-to-noise ratio (SNR). Oversampling, however, does not improve the integral non-linearity (INL), or differential non-linearity (DNL).

Oversampling and Scan mode should not be combined, since oversampling and scan will average over input channels.

The accumulator is controlled in the OVERSAMPLE register. The SAMPLE task must be set  $2^{\text{OVERSAMPLE}}$  number of times before the result is written to RAM. This can be achieved by the following:

- Configuring a fixed sampling rate using the local timer or a general purpose timer and the PPI system to trigger a SAMPLE task
- Triggering SAMPLE  $2^{\text{OVERSAMPLE}}$  times from software
- Enabling BURST mode

CH[n].CONFIG.BURST can be enabled to avoid setting SAMPLE task  $2^{\text{OVERSAMPLE}}$  times. With BURST = 1 the ADC will sample the input  $2^{\text{OVERSAMPLE}}$  times as fast as it can (actual timing:  $<(t_{\text{ACQ}}+t_{\text{CONV}}) \times 2^{\text{OVERSAMPLE}})$ ). Thus, for the user it will just appear like the conversion took a bit longer time, but other than that, it is similar to One-shot mode.

A DONE event signals that one sample has been taken.

In this mode, the RESULTDONE event signals that enough conversions have taken place for an oversampled result to get transferred into RAM. Both events may occur before the actual value has been transferred into RAM by EasyDMA.

### 7.29.5.4 Scan mode

A channel is considered enabled if CH[n].PSEL is set. If more than one channel, CH[n], is enabled, the ADC enters Scan mode.

In Scan mode, one SAMPLE task will trigger one conversion per enabled channel. The time it takes to sample all channels is given by the following equation:

$$\text{Total time} < \text{Sum}(\text{CH}[x].t_{\text{ACQ}}+t_{\text{CONV}}), \quad x=0..\text{enabled channels}$$

A DONE event signals that one sample has been taken.

In this mode, the RESULTDONE event signals has the same meaning as DONE when no oversampling takes place. Both events may occur before the actual values have been transferred into RAM by EasyDMA.

The following figure shows an example of the placement of results in Data RAM, with an even RESULT.MAXCNT. In this example, channels 1, 2, and 5 are enabled, all others are disabled.

|                                       | 31                           | 16 | 15                           | 0 |
|---------------------------------------|------------------------------|----|------------------------------|---|
| RESULT.PTR                            | CH[2] 1 <sup>st</sup> result |    | CH[1] 1 <sup>st</sup> result |   |
| RESULT.PTR + 4                        | CH[1] 2 <sup>nd</sup> result |    | CH[5] 1 <sup>st</sup> result |   |
| RESULT.PTR + 8                        | CH[5] 2 <sup>nd</sup> result |    | CH[2] 2 <sup>nd</sup> result |   |
|                                       | (...)                        |    |                              |   |
| RESULT.PTR +<br>2*(RESULT.MAXCNT - 2) | CH[5] last result            |    | CH[2] last result            |   |

Figure 196: Example of RAM placement (even RESULT.MAXCNT), channels 1, 2 and, 5 enabled

The following figure shows an example of the placement of results in Data RAM, with an odd RESULT.MAXCNT. In this example, channels 1, 2 and, 5 are enabled, all others are disabled. The last 32-bit word is populated only with one 16-bit result.

|                                       | 31                           | 16 | 15                           | 0 |
|---------------------------------------|------------------------------|----|------------------------------|---|
| RESULT.PTR                            | CH[2] 1 <sup>st</sup> result |    | CH[1] 1 <sup>st</sup> result |   |
| RESULT.PTR + 4                        | CH[1] 2 <sup>nd</sup> result |    | CH[5] 1 <sup>st</sup> result |   |
| RESULT.PTR + 8                        | CH[5] 2 <sup>nd</sup> result |    | CH[2] 2 <sup>nd</sup> result |   |
|                                       | ( ... )                      |    |                              |   |
| RESULT.PTR +<br>2*(RESULT.MAXCNT – 1) |                              |    | CH[5] last result            |   |

Figure 197: Example of RAM placement (odd RESULT.MAXCNT), channels 1, 2 and, 5 enabled

### 7.29.6 EasyDMA

After configuring RESULT.PTR and RESULT.MAXCNT, the ADC resources are started by triggering the START task. The ADC is using EasyDMA to store results in a Result buffer in RAM.

The Result buffer is located at the address specified in the RESULT.PTR register. The RESULT.PTR register is double-buffered and it can be updated and prepared for the next START task immediately after the STARTED event is generated. The size of the Result buffer is specified in the RESULT.MAXCNT register and the ADC will generate an END event when it has filled up the Result buffer, see [ADC](#) on page 593. Results are stored in little-endian byte order in Data RAM. Every sample will be sign extended to 16 bit before stored in the Result buffer.

The ADC is stopped by triggering the STOP task. The STOP task will terminate an ongoing sampling. The ADC will generate a STOPPED event when it has stopped. If the ADC is already stopped when the STOP task is triggered, the STOPPED event will still be generated.

Figure 198: ADC

If the RESULT.PTR is not pointing to a RAM region accessible from the peripheral, an EasyDMA transfer may result in a HardFault and/or memory corruption. See [Memory](#) on page 21 for more information about the different memory regions.

The EasyDMA will have finished accessing the RAM when the END or STOPPED event has been generated.

The RESULT.AMOUNT register can be read following an END event or a STOPPED event to see how many results have been transferred to the Result buffer in RAM since the START task was triggered.

In Scan mode, SAMPLE tasks can be triggered once the START task is triggered. The END event is generated when the number of samples transferred to memory reaches the value specified by RESULT.MAXCNT. After an END event, the START task needs to be triggered again before new samples can be taken. By specifying  $\text{RESULT.MAXCNT} \geq \text{number of channels enabled}$ , the size of the Result buffer should be large enough for a minimum of one result from each of the enabled channels. See [Scan mode](#) on page 591 for more information.

### 7.29.7 Resistor ladder

The ADC has an internal resistor string for positive and negative input.

The resistors in the following figure are controlled in the CH[n].CONFIG.RESP and CH[n].CONFIG.RESN registers.

Figure 199: Resistor ladder for positive input

### 7.29.8 Reference

The ADC can use the following two references, controlled in the REFSEL field of the CH[n].CONFIG register.

- Internal reference
- VDD as reference

The internal reference results in an input range of  $\pm 0.6$  V on the ADC core. VDD as reference results in an input range of  $\pm VDD/4$  on the ADC core. The gain block can be used to change the effective input range of the ADC.

$$\text{Input range} = (+- 0.6 \text{ V or } \pm VDD/4) / \text{Gain}$$

For example, choosing VDD as reference, single ended input (grounded negative input), and a gain of 1/4 the input range is the following:

$$\text{Input range} = (VDD/4) / (1/4) = VDD$$

With internal reference, single ended input (grounded negative input), and a gain of 1/6 the input range is the following:

$$\text{Input range} = (0.6 \text{ V}) / (1/6) = 3.6 \text{ V}$$

The **AIN0** - **AIN7** inputs cannot exceed VDD, or be lower than VSS.

### 7.29.9 Acquisition time

To sample the input voltage, the ADC connects a capacitor to the input.

The acquisition time indicates how long the capacitor is connected, see TACQ field in register CH[n].CONFIG (n=0..7) on page 610. The required acquisition time depends on the source ( $R_{\text{source}}$ ) resistance. For high source resistance, the acquisition time should be increased. See the following table for more information.

Figure 200: Simplified ADC sample network

| TACQ [ $\mu$ s] | Maximum source resistance [kOhm] |
|-----------------|----------------------------------|
| 3               | 10                               |
| 5               | 40                               |
| 10              | 100                              |
| 15              | 200                              |
| 20              | 400                              |
| 40              | 800                              |

Table 63: Acquisition time

When using **VDDHDI5** as input, the acquisition time needs to be 10  $\mu$ s or higher.

### 7.29.10 Limits event monitoring

A channel can be event monitored by configuring limit register CH[n].LIMIT.

If the conversion result is higher than the defined high limit, or lower than the defined low limit, the appropriate event will get fired.

Figure 201: Example of limits monitoring on channel 'n'

The CH[n].LIMIT.HIGH shall always be higher than or equal to CH[n].LIMIT.LOW . In other words, an event can be generated only when the input signal has been sampled outside of the defined limits. It is not possible to generate an event when the input signal is inside a defined range by swapping high and low limits.

The comparison to limits always takes place, there is no need to enable it. If comparison is not required on a channel, the software shall simply ignore the related events. In that situation, the value of the limits registers is irrelevant, so it does not matter if CH[n].LIMIT.LOW is lower than CH[n].LIMIT.HIGH or not.

## 7.29.11 Registers

### Instances

| Instance   | Domain      | Base address | TrustZone |     |     | Split<br>access | Description                                          |

### 7.29.11.33 OVERSAMPLE

Address offset: 0x5F4

Oversampling configuration. OVERSAMPLE should not be combined with SCAN. The RESOLUTION is applied before averaging, thus for high OVERSAMPLE a higher RESOLUTION should be used.

  ### 7.29.13 Performance factors

Clock jitter, affecting sample timing accuracy, and circuit noise can affect ADC performance.

Jitter can be between START tasks or from START task to acquisition. START timer accuracy and startup times of regulators and references will contribute to variability. Sources of circuit noise may include CPU activity and the DC/DC regulator. The best ADC performance is achieved using START timing based on the TIMER module, HFXO clock source, and Constant Latency mode.

## 7.30 SPIM — Serial peripheral interface master with EasyDMA

The SPI master can communicate with multiple SPI slaves using individual chip select signals for each slave.

The the main features of SPIM are:

- EasyDMA direct transfer to/from RAM
- SPI mode 0-3
- Individual selection of I/O pins
- Optional D/CX output line for distinguishing between command and data bytes

<sup>22</sup> Temperature drift is not included.

<sup>23</sup> Maximum gain corresponds to highest capacitance.

Figure 202: SPIM — SPI master with EasyDMA

### 7.30.1 SPI master transaction sequence

An SPI master transaction is started by triggering the START task. When started, a number of bytes will be transmitted/received on MOSI/MISO.

The following figure illustrates an SPI master transaction.

Figure 203: SPI master transaction

The ENDTX is generated when all bytes in buffer `TXD.PTR` on page 630 are transmitted. The number of bytes in the transmit buffer is specified in register `TXD.MAXCNT` on page 630. The ENDRX event will be generated when buffer `RXD.PTR` on page 629 is full, that is when the number of bytes specified in register `RXD.MAXCNT` on page 629 have been received. The transaction stops automatically after all bytes have been transmitted/received. When the maximum number of bytes in receive buffer is larger than the number of bytes in the transmit buffer, the contents of register `ORC` on page 633 will be transmitted after the last byte in the transmit buffer has been transmitted.

The END event will be generated after both the ENDRX and ENDTX events have been generated.

The SPI master can be stopped by triggering the STOP task. A STOPPED event is generated when the SPI master has stopped. If the STOP task is triggered in the middle of a transaction, SPIM will complete the transmission/reception of the current byte before stopping. The STOPPED event is generated even if the STOP task is triggered while there is no ongoing transaction.

If the ENDTX event has not already been generated when the SPI master has come to a stop, the ENDTX event will be generated even if all bytes in the buffer `TXD.PTR` on page 630 have not been transmitted.

If the ENDRX event has not already been generated when the SPI master has come to a stop, the ENDRX event will be generated even if the buffer `RXD.PTR` on page 629 is not full.

A transaction can be suspended and resumed using the SUSPEND and RESUME tasks, receptively. When the SUSPEND task is triggered, the SPI master will complete transmitting and receiving the current ongoing byte before it is suspended.

### 7.30.2 D/CX functionality

Some SPI slaves, for example display drivers, require an additional signal from the SPI master to distinguish between command and data bytes. For display drivers this line is often called D/CX.

The SPIM provides support for such a D/CX output line. The D/CX line is set low during transmission of command bytes and high during transmission of data bytes.

The D/CX pin number is selected using `PSELDCX` on page 632 and the number of command bytes preceding the data bytes is configured using `DCXCNT` on page 632.

It is not allowed to write to the `DCXCNT` on page 632 during an ongoing transmission.

The following figure shows the use of D/CX, using `SPIM.DCXCNT=1`.

Figure 204: D/CX example. SPIM.DCXCNT = 1.

### 7.30.3 Pin configuration

The SCK, CSN, DCX, MOSI, and MISO signals associated with the SPIM are mapped to physical pins according to the configuration specified in the PSEL.n registers.

The contents of registers [PSEL.SCK](#) on page 627, [PSEL.CSN](#) on page 628, [PSELDGX](#) on page 632, [PSEL.MOSI](#) on page 627, and [PSEL.MISO](#) on page 628 are only used when the SPIM is enabled and retained only as long as the device is in System ON mode. The PSEL.n registers can only be configured when the SPIM is disabled. Enabling/disabling is done using register [ENABLE](#) on page 627.

To ensure correct behavior, the pins used by the SPIM must be configured in the GPIO peripheral as described in [GPIO configuration](#) on page 617 before the SPIM is enabled. Make sure to activate the dedicated peripheral setting of the GPIO pin. See [GPIO — General purpose input/output](#) on page 293 for details on how to assign pins between cores, peripherals, or subsystems. For pin recommendations, see [Pin assignments](#) on page 851.

Only one peripheral can be assigned to drive a particular GPIO pin at a time. Failing to do so may result in unpredictable behavior.

| SPI master signal | SPI master pin                                        | Direction | Output value        |
|-------------------|-------------------------------------------------------|-----------|---------------------|
| SCK               | As specified in <a href="#">PSEL.SCK</a> on page 627  | Output    | Same as CONFIG.CPOL |
| CSN               | As specified in <a href="#">PSEL.CSN</a> on page 628  | Output    | Same as CONFIG.CPOL |
| DCX               | As specified in <a href="#">PSELDGX</a> on page 632   | Output    | 1                   |
| MOSI              | As specified in <a href="#">PSEL.MOSI</a> on page 627 | Output    | 0                   |
| MISO              | As specified in <a href="#">PSEL.MISO</a> on page 628 | Input     | Not applicable      |

Table 64: GPIO configuration

Some SPIM instances do not support automatic control of CSN, and for those the available GPIO pins need to be used to control CSN directly. See [Instances](#) on page 619 for information about what features are supported in the various SPIM instances.

The SPIM supports SPI modes 0 through 3. The clock polarity (CPOL) and the clock phase (CPHA) are configured in register [CONFIG](#) on page 631.

| Mode      | Clock polarity  | Clock phase  |
|-----------|-----------------|--------------|
|           | CPOL            | CPHA         |
| SPI_MODE0 | 0 (Active High) | 0 (Leading)  |
| SPI_MODE1 | 0 (Active High) | 1 (Trailing) |
| SPI_MODE2 | 1 (Active Low)  | 0 (Leading)  |
| SPI_MODE3 | 1 (Active Low)  | 1 (Trailing) |

Table 65: SPI modes

### 7.30.4 Shared resources

The SPI shares registers and other resources with other peripherals that have the same ID as the SPI. Therefore, the user must disable all peripherals that have the same ID as the SPI before the SPI can be configured and used.

Disabling a peripheral that has the same ID as the SPI will not reset any of the registers that are shared with the SPI. It is therefore important to configure all relevant SPI registers explicitly to secure that it operates correctly.

See the Instantiation table in [Peripherals](#) on page 149 for details on peripherals and their IDs.

### 7.30.5 EasyDMA

SPIM implements EasyDMA for accessing RAM without CPU involvement.

SPIM implements the following EasyDMA channels.

| Channel | Type   | Register Cluster    |
|---------|--------|---------------------|
| TXD     | READER | <a href="#">TXD</a> |
| RXD     | WRITER | <a href="#">RXD</a> |

Table 66: SPIM EasyDMA Channels

For detailed information regarding the use of EasyDMA, see [EasyDMA](#) on page 153.

The .PTR and .MAXCNT registers are double-buffered. They can be updated and prepared for the next transmission immediately after having received the STARTED event.

The SPI master will automatically stop transmitting after TXD.MAXCNT bytes have been transmitted and RXD.MAXCNT bytes have been received. If RXD.MAXCNT is larger than TXD.MAXCNT, the remaining transmitted bytes will contain the value defined in the ORC register. If TXD.MAXCNT is larger than RXD.MAXCNT, the additional received bytes will be discarded.

The ENDRX/ENDTX events indicate that EasyDMA has finished accessing respectively the RX/TX buffer in RAM. The END event gets generated when both RX and TX are finished accessing the buffers in RAM.

If several AHB bus masters try to access the same AHB slave at the same time, AHB bus congestion might occur, and the behavior of the EasyDMA channel will depend on the SPIM instance. Refer to [Instances](#) on page 619 for information about what behavior is supported in the various instances.

### 7.30.6 Low power

To ensure lowest possible power consumption when the peripheral is not needed stop and disable SPIM.

The STOP task may not be always needed (the peripheral might already be stopped), but if it is sent, software shall wait until the STOPPED event was received as a response before disabling the peripheral through the ENABLE register.

## 7.30.7 Registers

### Instances

| Instance   | Domain      | Base address | TrustZone |     |     | Split access | Description               |
|------------|-------------|--------------|-----------|-----|-----|--------------|---------------------------|
|            |             |              | Map       | Att | DMA |              |                           |
| SPIM0 : S  | APPLICATION | 0x50008000   | US        | S   | SA  | No           | SPI master 0              |
| SPIM0 : NS |             | 0x40008000   |           |     |     |              |                           |
| SPIM1 : S  | APPLICATION | 0x50009000   | US        | S   | SA  | No           | SPI master 1              |

### 7.30.7.22 STALLSTAT

Address offset: 0x400

Stall status for EasyDMA RAM accesses. The fields in this register are set to STALL by hardware whenever a stall occurs and can be cleared (set to NOSTALL) by the CPU.

| A                | RW  | RXDELAY |          | [7..0]                                                                                | Sample delay for input serial data on MISO. The value specifies the number of 64 MHz clock cycles (15.625 ns) delay from the the sampling edge of SCK (leading edge for CONFIG.CPHA = 0, trailing edge for CONFIG.CPHA = 1) until the input serial data is sampled. As an example, if RXDELAY = 0 and CONFIG.CPHA = 0, the input serial data is sampled on the rising edge of SCK. |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

<sup>24</sup> High bit rates may require GPIOs to be set as High Drive, see GPIO chapter for more details.

<sup>25</sup> Application core SPIM4 supports 32 Mbps write speed when running at 128 MHz.

<sup>26</sup> At 25pF load, including GPIO pin capacitance, see GPIO spec.

Figure 205: SPIM timing diagram

## 7.31 SPIS — Serial peripheral interface slave with EasyDMA

SPI slave (SPIS) is implemented with EasyDMA support for ultra-low power serial communication from an external SPI master. EasyDMA in conjunction with hardware-based semaphore mechanisms removes all real-time requirements associated with controlling the SPI slave from a low priority CPU execution context.

Figure 206: SPI slave

SPIS supports SPI modes 0 through 3. The CONFIG register allows setting CPOL and CPHA appropriately.

| Mode      | Clock polarity  | Clock phase       |
|-----------|-----------------|-------------------|
|           | CPOL            | CPHA              |
| SPI_MODE0 | 0 (Active High) | 0 (Trailing Edge) |
| SPI_MODE1 | 0 (Active High) | 1 (Leading Edge)  |
| SPI_MODE2 | 1 (Active Low)  | 0 (Trailing Edge) |
| SPI_MODE3 | 1 (Active Low)  | 1 (Leading Edge)  |

Table 67: SPI modes

### 7.31.1 Shared resources

The SPI slave shares registers and other resources with other peripherals that have the same ID as the SPI slave. Therefore, you must disable all peripherals that have the same ID as the SPI slave before the SPI slave can be configured and used.

Disabling a peripheral that has the same ID as the SPI slave will not reset any of the registers that are shared with the SPI slave. It is important to configure all relevant SPI slave registers explicitly to secure that it operates correctly.

The Instantiation table in [Peripherals](#) on page 149 shows which peripherals have the same ID as the SPI slave.

### 7.31.2 EasyDMA

SPIS implements EasyDMA for accessing RAM without CPU involvement.

SPIS implements the EasyDMA channels found in the following table.

| Channel | Type   | Register Cluster    |
|---------|--------|---------------------|
| TXD     | READER | <a href="#">TXD</a> |
| RXD     | WRITER | <a href="#">RXD</a> |

Table 68: SPIS EasyDMA Channels

For detailed information regarding the use of EasyDMA, see [EasyDMA](#) on page 153.

If RXD.MAXCNT is larger than TXD.MAXCNT, the remaining transmitted bytes will contain the value defined in the ORC register.

The END event indicates that EasyDMA has finished accessing the buffer in RAM.

### 7.31.3 SPI slave operation

SPI slave uses two memory pointers, RXD.PTR and TXD.PTR, that point to the RXD buffer (receive buffer) and TXD buffer (transmit buffer) respectively. Since these buffers are located in RAM, which can be accessed by both the SPI slave and the CPU, a hardware based semaphore mechanism is implemented to enable safe sharing.

Before the CPU can safely update the RXD.PTR and TXD.PTR pointers it must first acquire the SPI semaphore. The CPU can acquire the semaphore by triggering the ACQUIRE task and then receiving the ACQUIRED event. When the CPU has updated the RXD.PTR and TXD.PTR pointers the CPU must release the semaphore before the SPI slave will be able to acquire it.

The CPU releases the semaphore by triggering the RELEASE task, this is illustrated in [SPI transaction when shortcut between END and ACQUIRE is enabled](#) on page 637. Triggering the RELEASE task when the semaphore is not granted to the CPU will have no effect. See [Semaphore operation](#) on page 637 for more information

If the CPU is not able to reconfigure the TXD.PTR and RXD.PTR between granted transactions, the same TX data will be clocked out and the RX buffers will be overwritten. To prevent this from happening, the END\_ACQUIRE shortcut can be used. With this shortcut enabled, the semaphore will be handed over to the CPU automatically after the granted transaction has completed, giving the CPU the ability to update the TXPTR and RXPTR between every granted transaction.

The ENDRX event is generated when the RX buffer has been filled.

The RXD.MAXCNT register specifies the maximum number of bytes the SPI slave can receive in one granted transaction. If the SPI slave receives more than RXD.MAXCNT number of bytes, an OVERFLOW will be indicated in the STATUS register and the incoming bytes will be discarded.

The TXD.MAXCNT parameter specifies the maximum number of bytes the SPI slave can transmit in one granted transaction. If the SPI slave is forced to transmit more than TXD.MAXCNT number of bytes, an OVERREAD will be indicated in the STATUS register and the ORC character will be clocked out.

The RXD.AMOUNT and TXD.AMOUNT registers are updated when a granted transaction is completed. The TXD.AMOUNT register indicates how many bytes were read from the TX buffer in the last transaction, that is, ORC (over-read) characters are not included in this number. Similarly, the RXD.AMOUNT register indicates how many bytes were written into the RX buffer in the last transaction.

Figure 207: SPI transaction when shortcut between END and ACQUIRE is enabled

### 7.31.4 Semaphore operation

The semaphore is a mechanism implemented inside the SPI slave that prevents simultaneous access to the data buffers by the SPI slave and CPU.

The semaphore is by default assigned to the CPU after the SPI slave is enabled. No ACQUIRED event will be generated for this initial semaphore handover. An ACQUIRED event will be generated immediately if the ACQUIRE task is triggered while the semaphore is assigned to the CPU. The figure [SPI semaphore FSM](#) on page 638 illustrates the transitions between states in the semaphore based on the relevant tasks and events.

Figure 208: SPI semaphore FSM

**Note:** The semaphore mechanism does not, at any time, prevent the CPU from performing read or write access to the RXD.PTR register, the TXD.PTR registers, or the RAM that these pointers are pointing to. The semaphore is only telling when these can be updated by the CPU so that safe sharing is achieved.

The SPI slave will try to acquire the semaphore when STARTED event is detected, the event also indicates that CSN is currently low. If the SPI slave does not manage to acquire the semaphore at this point (i.e., it is under CPU's control), the transaction will be ignored. This means that all incoming data on MOSI will be discarded, and the DEF (default) character will be clocked out on the MISO line throughout the whole transaction. This will also be the case even if the semaphore is released by the CPU during the transaction. In case of a race condition where the CPU and the SPI slave try to acquire the semaphore at the same time, as illustrated in lifeline item 2 in figure [SPI transaction when shortcut between END and ACQUIRE is enabled](#) on page 637, the semaphore will be granted to the CPU.

If the SPI slave acquires the semaphore, the transaction will be granted. The incoming data on MOSI will be stored in the RXD buffer and the data in the TXD buffer will be clocked out on MISO.

When a granted transaction is completed and CSN goes high, the SPI slave will automatically release the semaphore and generate the END event.

As long as the semaphore is available, the SPI slave can be granted multiple transactions one after the other.

If the CPU tries to acquire the semaphore while it is assigned to the SPI slave, an immediate handover will not be granted. However, the semaphore will be handed over to the CPU as soon as the SPI slave has released the semaphore after the granted transaction is completed. If the END\_ACQUIRE shortcut is enabled and the CPU has triggered the ACQUIRE task during a granted transaction, only one ACQUIRE request will be served following the END event.

### 7.31.5 Pin configuration

The CSN, SCK, MOSI, and MISO signals associated with the SPI slave are mapped to physical pins according to the configuration specified in the PSEL.CSN, PSEL.SCK, PSEL.MOSI, and PSEL.MISO registers respectively. If the CONNECT field of any of these registers is set to Disconnected, the associated SPI slave signal will not be connected to any physical pins.

The PSEL.CSN, PSEL.SCK, PSEL.MOSI, and PSEL.MISO registers and their configurations are only used as long as the SPI slave is enabled, and retained only as long as the device is in System ON mode, see [POWER — Power control](#) on page 46 chapter for more information about power modes. When the peripheral is disabled, the pins will behave as regular GPIOs, and use the configuration in their respective OUT bit field

and PIN\_CNF[n] register. PSEL.CSN, PSEL.SCK, PSEL.MOSI, and PSEL.MISO must only be configured when the SPI slave is disabled.

To secure correct behavior in the SPI slave, the pins used by the SPI slave must be configured in the GPIO peripheral as described in [GPIO configuration before enabling peripheral](#) on page 639 before enabling the SPI slave. This is to secure that the pins used by the SPI slave are driven correctly if the SPI slave itself is temporarily disabled, or if the device temporarily enters System OFF. This configuration must be retained in the GPIO for the selected I/Os as long as the SPI slave is to be recognized by an external SPI master.

The MISO line is set in high impedance as long as the SPI slave is not selected with CSN.

Only one peripheral can be assigned to drive a particular GPIO pin at a time. Failing to do so may result in unpredictable behavior.

| SPI signal | SPI pin                   | Direction | Output value   | Comment                                      |
|------------|---------------------------|-----------|----------------|----------------------------------------------|
| CSN        | As specified in PSEL.CSN  | Input     | Not applicable |                                              |
| SCK        | As specified in PSEL.SCK  | Input     | Not applicable |                                              |
| MOSI       | As specified in PSEL.MOSI | Input     | Not applicable |                                              |
| MISO       | As specified in PSEL.MISO | Input     | Not applicable | Emulates that the SPI slave is not selected. |

| $t_{\text{SPIS,CWH}}$    | CSN inactive time                               | 300                |      |      | ns    |
| $t_{\text{SPIS,VSO}}$    | CLK edge to MISO valid                          |                    |      | 53   | ns    |
| $t_{\text{SPIS,VSO,HD}}$ | CLK edge to MISO valid, GPIO in high drive mode |                    |      | 40   | ns    |
| $t_{\text{SPIS,HSO}}$    | MISO hold time after CLK edge                   | 13                 |      |      | ns    |
| $t_{\text{SPIS,SUSI}}$   | MOSI to CLK edge setup time                     | 19                 |      |      | ns    |
| $t_{\text{SPIS,HSI}}$    | CLK edge to MOSI hold time                      | 10                 |      |      | ns    |

<sup>27</sup> High bit rates may require GPIOs to be set as High Drive, see GPIO chapter for more details.

<sup>28</sup> The actual maximum data rate depends on the master's CLK to MISO and MOSI setup and hold timings.

<sup>29</sup> Excluding any start-up delay for the high frequency clock in low power mode.

<sup>30</sup> At 25pF load, including GPIO capacitance, see GPIO spec.

Figure 209: SPIS timing diagram

Figure 210: Common SPIM and SPIS timing diagram

## 7.32 SPU — System protection unit

SPU is the central point in the system to control access to memories, peripherals and other resources.

The main features of SPU are the following:

- Arm TrustZone support, allowing definition of secure, non-secure and non-secure callable memory regions
- Extended Arm TrustZone, protecting memory regions and peripherals from non-CPU devices like EasyDMA transfer
- Pin access protection, preventing non-secure code and peripherals from accessing secure pin resources
- DPPI access protection, realized by preventing non-secure code and peripherals to publish from or subscribe to secured DPPI channels
- External domain access protection, controlling access rights from other MCUs

### 7.32.1 General concepts

SPU provides a register interface to control the various internal logic blocks that monitor access to memory-mapped slave devices (RAM, flash, peripherals, etc) and other resources (device pins, DPPI channels, etc).

For memory-mapped devices like RAM, flash, and peripherals, the internal logic checks the address and attributes (e.g. read, write, execute, secure) of the incoming transfer to block it if necessary. A secure resource can be accessed by a given master based on the following factors:

- *CPU-type master* – By the security state of the CPU and the security state reported by SPU, for the address in the bus transfer.
- *Non-CPU master* – By the security attribute of the master that initiates the transfer, defined by a SPU register.

The [Simplified view of SPU protection](#) on page 651 shows a simplified view of the SPU registers controlling several internal modules.

Figure 211: Simplified view of SPU protection

The protection logic implements a read-as-zero/write-ignore (RAZ/WI) policy where the following are true:

- A blocked read operation will always return a zero value on the bus, preventing information leak.
- A write operation to a forbidden region or peripheral will be ignored.

An error is reported through dedicated error signals. For security state violations from an M33 master this will be a SecureFault exception, for other violations this will be an SPU event. The SPU event can be configured to generate an interrupt towards the CPU.

Other resources like pins and DPPI channels are protected by comparing the security attributes of the protected resource with the security attribute of the peripheral that wants to access it. SPU is the only place where those security attributes can be configured.

### 7.32.1.1 Special considerations for Arm TrustZone for Cortex-M enabled system

SPU also controls custom logic for an Arm TrustZone for Cortex-M enabled CPU.

Custom logic is shown as the implementation defined attribution unit (IDAU) in figure [Simplified view of SPU protection](#) on page 651. Full support is provided for the following:

- Arm TrustZone for Cortex-M related instructions, like test target (TT) for reporting the security attributes of a region
- Non-secure callable (NSC) regions, to implement secure entry points from non-secure code

SPU provides the necessary registers to configure the security attributes for memory regions and peripherals. However, as a requirement to use SPU, the secure attribution unit (SAU) needs to be disabled and all memory set as non-secure in the Arm core. This will allow SPU to control the IDAU and set the security attribution of all addresses as originally intended.

### 7.32.2 Flash access control

The flash memory space is divided into 64 regions of 16 KiB, each with configurable permissions settings.

For each region, the following types of permissions can be configured:

#### Read

Allows data read access to the region. The code fetch from this region is not controlled by the read permission but by the execute permission described below.

#### Write

Allows write or page erase access to the region.

#### Execute

Allows code fetch from this region, even if data read is disabled.

#### Secure

Allows only bus accesses with the security attribute set to access the region.

Permissions can be set independently. For example, it is possible to configure a flash region to be accessible only through secure transfer, being read-only (no write allowed) and non-executable (no code fetch allowed). For each region, permissions can be set and then locked by using the [FLASHREGION\[n\].PERM.LOCK](#) bit, to prevent subsequent modifications.

The debugger can step through execute-protected memory regions.

The following figure shows the N=64 flash regions, each of size 16 KiB.

Figure 212: Flash memory regions

### 7.32.2.1 Non-secure callable (NSC) region definition in flash

SPU provides support for the definition of non-secure callable (NSC) sub-regions to allow non-secure to secure function calls.

A non-secure callable sub-region can only exist within an existing secure region and its definition is done using the following registers:

- `FLASHNSC[n].REGION`, used to select the secure region that will contain the NSC sub-region
- `FLASHNSC[n].SIZE`, used to define the size of the NSC sub-region within the secure region

The NSC sub-region will be defined starting with the highest address in that region and descending. The following figure illustrates the NSC sub-regions and the registers used for their definition.

Figure 213: Non-secure callable region definition in the flash memory space

The NSC sub-region will only be defined when the following are true:

- FLASHNSC[i].SIZE value is non zero
- FLASHNSC[i].REGION defines a secure region

If FLASHNSC[i].REGION and FLASHNSC[j].REGION have the same value, there is only one sub-region defined as NSC, with the size given by the maximum of FLASHNSC[i].SIZE and FLASHNSC[j].SIZE.

If FLASHNSC[i].REGION defines a non-secure region, then there is no non-secure callable region defined and the selected region stays non-secure.

### 7.32.2.2 Flash access error reporting

SPU and the logic controlled by it will respond with a certain behavior once an access violation is detected.

The following actions will happen once the logic controlled by SPU detects an access violation on one of the flash ports:

- The faulty transfer will be blocked.
- In case of a read transfer, the bus will be driven to zero.
- If supported by the master, feedback will be sent to the master through specific bus error signals. At the same time, SPU will receive an event that can optionally trigger a CPU interrupt.
- A SecureFault exception will be triggered if a security violation is detected for access from the CPU.
- A BusFault exception will be triggered when a read/write/execute protection violation is detected from the CPU.
- The FLASHACCERR event will be triggered if any access violations are detected for all master types except for the CPU security violation.

The following table summarizes the SPU behavior based on the type of initiator and access violation.

| Master type    | Security violation        | Read/Write/Execute protection violation |
|----------------|---------------------------|-----------------------------------------|
| Arm Cortex-M33 | SecureFault exception     | BusFault exception, FLASHACCERR event   |
| EasyDMA        | RAZ/WI, FLASHACCERR event | RAZ/WI, FLASHACCERR event               |
| Other masters  | RAZ/WI, FLASHACCERR event | RAZ/WI, FLASHACCERR event               |

Table 70: Error reporting for flash access errors

For the Arm Cortex-M33 master, the SecureFault exception will take precedence over the BusFault exception if a security violation occurs simultaneously with another type of violation.

### 7.32.2.3 UICR and FICR protections

The user information configuration registers (UICR) and factory information configuration registers (FICR) are always considered as secure. FICR registers are read-only. UICR registers can be read and written by secure code only.

Writing new values to user information configuration registers must follow the procedure described in [NVMC — Non-volatile memory controller](#) on page 400. Code execution from FICR and UICR address spaces will always be reported as an access violation except during a debug session.

## 7.32.3 RAM access control

The RAM memory space is divided into 64 regions of 8 KiB, each with configurable permissions settings.

For each region, the following types of permissions can be configured:

#### Read

Allows data read access to the region. Code fetch from this region is not controlled by the read permission but by the execute permission described below.

#### Write

Allows write access to the region.

#### Execute

Allows code fetch from this region.

#### Secure

Allows only bus accesses with the security attribute set to access the region.

Permissions can be set independently. For example, it is possible to configure a RAM region to be accessible only through secure transfer, being read-only (no write allowed) and non-executable (no code fetch allowed). For each region, permissions can be set and then locked to prevent subsequent modifications by using the [RAMREGION\[n\].PERM.LOCK](#) bit.

The following figure shows the RAM memory space divided into N=64 regions, each of 8 KiB.

Figure 214: RAM memory regions

### 7.32.3.1 Non-secure callable (NSC) region definition in RAM

SPU provides support for the definition of non-secure callable (NSC) sub-regions to allow non-secure to secure function calls.

A non-secure callable sub-region can only exist within an existing secure region. It is defined by the following registers:

- `RAMNSC[n].REGION`, used to select the secure region that will contain the NSC sub-region
- `RAMNSC[n].SIZE`, used to define the size of the NSC sub-region within the secure region

The NSC sub-region will be defined starting with the highest address in that region and descending. The following figure shows the NSC sub-regions and the registers used for their definition.

Figure 215: Non-secure callable region definition in the RAM memory space

The NSC sub-region will only be defined when the following are true:

- `RAMNSC[i].SIZE` value is non zero
- `RAMNSC[i].REGION` defines a secure region

If `RAMNSC[i].REGION` and `RAMNSC[j].REGION` have the same value, there is only one sub-region defined as NSC, with the size given by the maximum of `RAMNSC[i].SIZE` and `RAMNSC[j].SIZE`.

If `RAMNSC[i].REGION` defines a non-secure region, then there is no non-secure callable region defined and the selected region stays non-secure.

### 7.32.3.2 RAM access error reporting

SPU and the logic it controls will respond with a certain behavior once an access violation is detected.

The following actions will happen once the logic controlled by the SPU detects an access violation on one of the RAM ports:

- The faulty transfer will be blocked.
- In case of a read transfer, the bus will be driven to zero.
- If supported by the master, feedback will be sent to the master through specific bus error signals.
- A SecureFault exception will be triggered if security violation is detected for access from Arm Cortex-M33
- A BusFault exception will be triggered when read/write/execute protection violation is detected for Arm Cortex-M33. The SPU will also generate an event that can optionally trigger an interrupt towards the CPU.
- The RAMACCERR event will be triggered if any access violations are detected for all master types but for Arm Cortex-M33 security violation

The following table summarizes the SPU behavior based on the type of initiator and access violation.

| Master type    | Security violation      | Read/Write/Execute protection violation |
|----------------|-------------------------|-----------------------------------------|
| Arm Cortex-M33 | SecureFault exception   | BusFault exception, RAMACCERR event     |
| EasyDMA        | RAZ/WI, RAMACCERR event | RAZ/WI, RAMACCERR event                 |
| Other masters  | RAZ/WI, RAMACCERR event | RAZ/WI, RAMACCERR event                 |

Table 71: Error reporting for RAM access errors

For the Arm Cortex-M33 master, the SecureFault exception will take precedence over the BusFault exception if a security violation occurs simultaneously with another type of violation.

### 7.32.4 Peripheral access control

Access controls are defined by the characteristics of the peripheral.

Peripherals can have their security attribute set as one of the following:

#### Always secure

For a peripheral related to system control.

#### Always non-secure

For some general-purpose peripherals.

#### Configurable

For general-purpose peripherals that may be configured for secure only access.

The full list of peripherals and their corresponding security attributes can be found in [Memory](#) on page 21. For each peripheral with ID  $n$ , [PERIPHID\[n\].PERM](#) will show whether the security attribute for this peripheral is configurable or not.

If not hardcoded, the security attribute can be configured using the [PERIPHID\[id\].PERM](#).

At reset, all user-selectable and split security peripherals are set to be secure with secure DMA where present.

Secure code can access both secure peripherals and non-secure peripherals.

#### 7.32.4.1 Peripherals with split security

Peripherals with split security are defined to handle use-cases when both secure and non-secure code needs to control the same resource.

When peripherals with split security have their security attribute set to non-secure, access to specific registers and bitfields within some registers is dependent on the security attribute of the bus transfer. For example, some registers will not be accessible for a non-secure transfer.

When peripherals with split security have their security attribute set to secure, then only secure transfers can access their registers.

See [Peripherals](#) on page 149 for an overview of split security peripherals. Respective peripheral chapters explain the specific security behavior of each peripheral.

#### 7.32.4.2 Peripheral address mapping

Peripherals that have non-secure security mapping have their address starting with 0x4XXXXXXX.

Peripherals that have secure security mapping have their address starting with 0x5XXXXXXX.

Peripherals with a user-selectable security mapping are available at an address starting with the following:

- 0x4XXXXXXX, if the peripheral security attribute is set to non-secure
- 0x5XXXXXXX, if the peripheral security attribute is set to secure

**Note:**

Access to a secure peripheral using the 0x4XXXXXXX address range will result in bus error, regardless if the CPU is executing secure or non-secure code.

Similarly, a CPU running secure code attempting to access a non-secure peripheral using the 0x5XXXXXXX address range will result in bus error.

Peripherals with a split security mapping are available at an address starting with the following:

- 0x4XXXXXXX for non-secure access and 0x5XXXXXXX for secure access, if the peripheral security attribute is set to non-secure
  - Secure registers in the 0x4XXXXXXX range are not visible for secure or non-secure code, and an attempt to access such a register will result in write-ignore, read-as-zero behavior
  - Secure code can access both non-secure and secure registers in the 0x5XXXXXXX range
- 0x5XXXXXXX, if the peripheral security attribute is set to secure

Any attempt to access the 0x50000000 to 0x5FFFFFFF address range from non-secure code will be ignored and generate a SecureFault exception.

The following table contains the address mapping for the three peripheral types in each configuration.

| Security-features and configuration                  | Mapped at 0x4XXXXXXX?         | Mapped at 0x5XXXXXXX? |
|------------------------------------------------------|-------------------------------|-----------------------|
| Secure peripheral                                    | No                            | Yes                   |
| Non-secure peripheral                                | Yes                           | No                    |
| Split-security peripheral, with attribute=secure     | No                            | Yes                   |
| Split-security peripheral, with attribute=non-secure | Yes, restricted functionality | Yes                   |

Table 72: Peripheral's address mapping in relation to its security-features and configuration

### 7.32.4.3 Special considerations for peripherals with DMA master

Peripherals containing a DMA master can be configured so the security attribute of the DMA transfers is different from the security attribute of the peripheral itself. This allows a secure peripheral to do non-secure data transfers to or from the system memories.

The following conditions must be met:

- The DMA field of `PERIPHID[n].PERM.SECURITYMAPPING` should read as "SeparateAttribute"
- The peripheral itself should be secure (`PERIPHID[n].PERM.SECATTR == 1`)

Then it is possible to select the security attribute of the DMA transfers using the field `DMASEC` (`PERIPHID[n].PERM.DMASEC == Secure` and `PERIPHID[n].PERM.DMASEC == NonSecure`) in `PERIPHID[n].PERM`.

### 7.32.4.4 Peripheral access error reporting

Peripherals send error reports once access violation is detected.

The following actions will happen if the logic controlled by the SPU detects an access violation on one of the peripherals:

- The faulty transfer will be blocked.
- In case of a read transfer, the bus will be driven to zero.
- If supported by the master, feedback is sent to the master through specific bus error signals. If the master is a processor supporting Arm TrustZone for Cortex-M, a SecureFault exception will be generated for security related errors.
- The `PERIPHACCERR` event will be triggered.

### 7.32.5 Pin access control

Access to device pins can be controlled by SPU. A pin can be declared as secure so that only secure peripherals or secure code can access it. Pins declared as non-secure can be accessed by both secure and non-secure peripherals or code.

The security attribute of each pin can be individually configured in SPU's `GPIOPORT[n].PERM` register. When the secure attribute is set for a pin, only peripherals that have the secure attribute set will be able to read the value of the pin or change it.

Peripherals can select the pins they need access to through their PSEL registers. If a peripheral has its attribute set to non-secure, but one of its PSEL registers selects a pin with the attribute set to secure, the SPU controlled logic will ensure that the pin selection is not propagated. In addition, the pin value will always be read as zero, to prevent a non-secure peripheral from obtaining a value from a secure pin. Access to other pins with attribute set as non-secure will not be blocked.

Pins can be assigned to other domains than the application domain by changing the MCUSEL value in the GPIO `PIN_CNFG[n]` register. Domains that do not have a pin assigned to them cannot control a pin or read its status. Any pin configuration set in a domain that doesn't have ownership of that pin will not take effect until the MCUSEL is updated to assign that pin to the domain. Within each domain, pin access is controlled by that domain's local security configuration and peripheral PSEL registers. This is illustrated in the following figure:

The SPU setting will still count when the APP domain accesses its local GPIO peripheral, as local registers are still writable even though MCUSEL is set to a different domain. Any changes in the APP GPIO peripheral done to a GPIO controlled by another domain will not affect the GPIO pad until MCUSEL is changed to APP.

Figure 216: Pin access for domains other than the application domain

### 7.32.6 DPPI access control

Access to DPPI channels can be restricted. A channel can be declared as secure so that only secure peripherals can access it.

The security attribute of a DPPI channel is configured in `DPPI[n].PERM (n=0..0)` on page 670. When the secure attribute is set for a channel, only peripherals that have the secure attribute set will be able to publish events to this channel or subscribe to this channel to receive tasks.

The DPPI controller peripheral (DPPIC) is a split security peripheral, i.e., its security behavior depends on the security attributes of both the DPPIC and the accessing party. See [Special considerations regarding the DPPIC configuration registers](#) on page 661 for more information about the DPPIC security behavior.

If a non-secure peripheral wants to publish an event on a secure DPPI channel, the channel will ignore the event. If a non-secure peripheral subscribes to a secure DPPI channel, it will not receive any events from this channel. The following figure illustrates the principle of operation of the security logic for a subscribed channel:

Figure 217: Subscribed channel security concept

No error reporting mechanism is associated with the DPPI access control logic.

### 7.32.6.1 Special considerations regarding the DPPIC configuration registers

DPPI channels can be enabled, disabled and grouped through the DPPI controller (DPPIC). The DPPIC is a split-security peripheral, and handles both secure and non-secure accesses.

A non-secure peripheral access will only be able to configure and control DPPI channels defined as non-secure in SPU's `DPPI[n].PERM` register(s). A secure peripheral access can control all DPPI channels, independently of the configuration in the `DPPI[n].PERM` register(s).

The DPPIC allows the creation of group of channels to be able to enable or disable all channels within a group simultaneously. The security attribute of a group of channels (secure or non-secure) is defined as follows:

- If all channels (enabled or not) in the group are non-secure, then the group is considered non-secure
- If at least one of the channels (enabled or not) in the group is secure, then the group is considered secure

A non-secure access to a DPPIC register, or a bitfield controlling a channel marked as secure in `DPPI[n].PERM` register(s), will be ignored:

- Write accesses will have no effect
- Read will always return a zero value

No exceptions are thrown when a non-secure access targets a register or bitfield controlling a secure channel. For example, if the bit *i* is set in the `DPPI[n].PERM` register (declaring the DPPI channel *i* as secure), then:

- Non-secure write accesses to registers CHEN, CHENSET and CHENCLR will not be able to write to bit  $i$  of those registers
- Non-secure write accesses to registers TASK\_CHG[j].EN and TASK\_CHG[j].DIS will be ignored if the channel group  $j$  contains at least one channel defined as secure (it can be the channel  $i$  itself or any channel declared as secured)
- Non-secure read accesses to registers CHEN, CHENSET and CHENCLR will always read zero for the bit at position  $i$

For the channel configuration registers (DPPIC.CHG[n]), access from non-secure code is only possible if the included channels are all non-secure, whether the channels are enabled or not. If a DPPIC.CHG[g] register included one or more secure channels, then the group  $g$  is considered as secure and only a secure transfer can read or write DPPIC.CHG[g]. A non-secure write will be ignored and a non-secure read will return zero.

The DPPIC can subscribe to secure or non-secure channels through SUBSCRIBE\_CHG[n] registers in order to trigger task for enabling or disabling groups of channels. But an event from a non-secure channel will be ignored if the group subscribing to this channel is secure. An event from a secure channel can trigger both secure and non-secure tasks.

### 7.32.7 External domain access control

Other domains with their own CPUs can access peripherals, flash and RAM memories. The SPU allows controlling accesses from those bus masters.

The external domains can access application MCU memories and peripherals. External domains are assigned security attributes as described in register EXTDOMAIN[n].PERM.

| Domain      | Capability register                                         | Permission register                                   |
|-------------|-------------------------------------------------------------|-------------------------------------------------------|
| Network MCU | EXTDOMAIN[n].PERM (n=0..0) on page 669, SECUREMAPPING field | EXTDOMAIN[n].PERM (n=0..0) on page 669, SECATTR field |

Table 73: Register mapping for external domains

The figure below illustrates how the security control units are used to assign security attributes to transfers initiated by the external domains:

Figure 218: Access control from external domains

### 7.32.8 Arm TrustZone for Cortex-M ID allocation

Flash and RAM regions, as well as non-secure and secure peripherals, are assigned unique Arm TrustZone IDs.

The Arm TrustZone ID should not be mistaken for the peripheral ID used to identify peripherals.

The following table lists the Arm TrustZone ID allocation.

| Regions                | Arm TrustZone Cortex-M ID |
|------------------------|---------------------------|
| Flash regions 0..63    | 0..63                     |
| RAM regions 0..63      | 64..127                   |
| UICR                   | 252                       |
| FICR                   | 252                       |
| CACHEDATA              | 252                       |
| CACHEINFO              | 252                       |
| Non-secure peripherals | 253                       |
| Secure peripherals     | 254                       |

Table 74: Arm TrustZone ID allocation

## 7.32.9 Registers

### Instances

| Instance | Domain      | Base address | TrustZone |     |     | Split access | Description            |
|----------|-------------|--------------|-----------|-----|-----|--------------|------------------------|
|          |             |              | Map       | Att | DMA |              |                        |
| SPU      | APPLICATION | 0x50003000   | HF        | S   | NA  | No           | System protection unit |

### Register overview

| Register             | Offset | TZ | Description                                                                                                  |
|----------------------|--------|----|--------------------------------------------------------------------------------------------------------------|
| EVENTS_RAMACCERR     | 0x100  |    | A security violation has been detected for the RAM memory space                                              |
| EVENTS_FLASHACCERR   | 0x104  |    | A security violation has been detected for the flash memory space                                            |
| EVENTS_PERIPHACCERR  | 0x108  |    | A security violation has been detected on one or several peripherals                                         |
| PUBLISH_RAMACCERR    | 0x180  |    | Publish configuration for event <a href="#">RAMACCERR</a>                                                    |
| PUBLISH_FLASHACCERR  | 0x184  |    | Publish configuration for event <a href="#">FLASHACCERR</a>                                                  |
| PUBLISH_PERIPHACCERR | 0x188  |    | Publish configuration for event <a href="#">PERIPHACCERR</a>                                                 |
| INTEN                | 0x300  |    | Enable or disable interrupt                                                                                  |
| INTENSET             | 0x304  |    | Enable interrupt                                                                                             |
| INTENCLR             | 0x308  |    | Disable interrupt                                                                                            |
| CAP                  | 0x400  |    | Show implemented features for the current device                                                             |
| CPULOCK              | 0x404  |    | Configure bits to lock down CPU features at runtime                                                          |
| EXTDOMAIN[n].PERM    | 0x440  |    | Access for bus access generated from the external domain n<br><br>List capabilities of the external domain n |
| DPPI[n].PERM         | 0x480  |    | Select between secure and non-secure attribute for the DPPI channels                                         |
| DPPI[n].LOCK         | 0x484  |    | Prevent further modification of the corresponding PERM register                                              |
| GPIOPORT[n].PERM     | 0x4C0  |    | Select between secure and non-secure attribute for pins 0 to 31 of port n<br><br>This register is retained.  |
| GPIOPORT[n].LOCK     | 0x4C4  |    | Prevent further modification of the corresponding PERM register                                              |
| FLASHNSC[n].REGION   | 0x500  |    | Define which flash region can contain the non-secure callable (NSC) region n                                 |
| FLASHNSC[n].SIZE     | 0x504  |    | Define the size of the non-secure callable (NSC) region n                                                    |

### 7.32.9.11 CPULOCK

Address offset: 0x404

Configure bits to lock down CPU features at runtime

Write '1' to any position to set the corresponding lock bit, which will remain set until the next reset

Any '0' writes to this register will be ignored

### 7.33 SWI — Software interrupts

A set of interrupts have been reserved for use as software interrupts.

### 7.33.1 Registers

## Instances

| Instance | Domain  | Base address | TrustZone |     |     | Split<br>access | Description          |
|----------|---------|--------------|-----------|-----|-----|-----------------|----------------------|
|          |         |              | Map       | Att | DMA |                 |                      |
| SWI0     | NETWORK | 0x4101A000   | HF        | NS  | NA  | No              | Software interrupt 0 |
| SWI1     | NETWORK | 0x4101B000   | HF        | NS  | NA  | No              | Software interrupt 1 |
| SWI2     | NETWORK | 0x4101C000   | HF        | NS  | NA  | No              | Software interrupt 2 |
| SWI3     | NETWORK | 0x4101D000   | HF        | NS  | NA  | No              | Software interrupt 3 |

## 7.34 TEMP — Temperature sensor

The temperature sensor measures die temperature over the temperature range of the device. Linearity compensation can be implemented if required by the application.

The main features of TEMP are the following:

- Temperature range is greater than or equal to operating temperature of the device
- Resolution is 0.25 °C

TEMP is started by triggering the START task.

When the temperature measurement is completed, a DATARDY event will be generated and the result of the measurement can be read from the TEMP register.

To achieve the measurement accuracy stated in the electrical specification, the crystal oscillator must be selected as the HFCLK source, see [CLOCK — Clock control](#) on page 72 for more information.

When the temperature measurement is completed, TEMP analog electronics power down to save power.

TEMP only supports one-shot operation, meaning that every TEMP measurement has to be explicitly started using the START task.

### 7.34.1 Registers

#### Instances

| Instance | Domain  | Base address | TrustZone |     |     | Split access | Description        |
|----------|---------|--------------|-----------|-----|-----|--------------|--------------------|
|          |         |              | Map       | Att | DMA |              |                    |
| TEMP     | NETWORK | 0x41010000   | HF        | NS  | NA  | No           | Temperature sensor |

#### Register overview

| Register        | Offset | TZ | Description                                             |

| T <sub>TEMP,OFFST</sub>     | Sample offset at 25°C                                     | -2.5 |      | 2.5   | °C    |

## 7.35 TIMER — Timer/counter

This peripheral is a general purpose timer allowing time intervals to be defined by user input. It can operate in two modes: Timer mode and Counter mode.

Figure 219: Block schematic for timer/counter

TIMER runs on the high-frequency clock source (HFCLK) and includes a four-bit (1/2X) prescaler that can divide the timer input clock from the HFCLK controller. Clock source selection between PCLK16M and PCLK1M is automatic according to the TIMER base frequency set by the prescaler. The TIMER base frequency is always given as 16 MHz divided by the prescaler value.

The PPI system allows a TIMER event to trigger a task on another system peripheral on the device. The PPI system also enables the TIMER task/event feature to generate periodic output and PWM signals to any GPIO. The number of GPIO inputs or outputs used at the same time is limited by the number of GPIOTE channels.

TIMER can operate in two modes: Timer mode and Counter mode. In both modes, TIMER is started by triggering the START task, and stopped by triggering the STOP task. After TIMER stops, it can resume timing/counting by triggering the START task again. When timing/counting resumes, TIMER continues from the value it was on prior to stopping.

In Timer mode, TIMER's internal Counter register is incremented by one for every tick of the timer frequency  $f_{\text{TIMER}}$ , as illustrated in [Block schematic for timer/counter](#) on page 683. The timer frequency is derived from PCLK16M as shown in the following example, using the values specified in the PRESCALER register.

$$f_{\text{TIMER}} = 16 \text{ MHz} / (2^{\text{PRESCALER}})$$

When  $f_{\text{TIMER}} \leq 1 \text{ MHz}$ , TIMER uses PCLK1M instead of PCLK16M for reduced power consumption.

In Counter mode, the TIMER's internal Counter register is incremented by one each time the COUNT task is triggered, meaning the timer frequency and the prescaler are not utilized in Counter mode. Similarly, the COUNT task has no effect in Timer mode.

TIMER's maximum value is configured by changing the bit-width of the timer in register [BITMODE](#) on page 691.

[PRESCALER](#) on page 691 and [BITMODE](#) on page 691 must only be updated when TIMER is stopped. If these registers are updated while TIMER is started, unpredictable behavior may occur.

When TIMER is incremented beyond its maximum value, the Counter register will overflow and TIMER will automatically start over from zero.

The Counter register can be cleared by triggering the CLEAR task. This will explicitly set the internal value to zero.

TIMER implements multiple capture/compare registers.

Independent of prescaler settings, the accuracy of TIMER is equivalent to one tick of the timer frequency  $f_{\text{TIMER}}$  as illustrated in [Block schematic for timer/counter](#) on page 683.

### 7.35.1 Capture

TIMER implements one capture task for every available capture/compare register.

Every time the CAPTURE[n] task is triggered, the counter value is copied to the CC[n] register.

### 7.35.2 Compare

TIMER implements one COMPARE event for every available capture/compare register.

When the counter value becomes equal to the value specified in a capture compare register CC[n], the corresponding compare event COMPARE[n] is generated.

**BITMODE** on page 691 specifies how many Counter and capture/compare register bits are used when the comparison is performed. Other bits are ignored.

The COMPARE event can be configured to operate in one-shot mode by configuring the corresponding ONESHOTEN[n] register. After writing CC[n], a COMPARE[n] event is generated the first time the Counter matches CC[n].

### 7.35.3 Task delays

After TIMER is started, the CLEAR, COUNT, and STOP tasks are guaranteed to take effect within one clock cycle of the PCLK16M.

### 7.35.4 Task priority

If the START task and the STOP task are triggered at the same time, meaning within the same period of PCLK16M, the STOP task is prioritized.

If one or more of the CAPTURE tasks and the CLEAR task are triggered at the same time, that is, within the same period of PCLK16M, the CAPTURE tasks are prioritized. This means that the CC registers will capture the counter value before the CLEAR tasks are triggered.

### 7.35.5 Registers

#### Instances

## 7.36 TWIM — I<sup>2</sup>C compatible two-wire interface master with EasyDMA

TWI master with EasyDMA (TWIM) is a two-wire half-duplex master which can communicate with multiple slave devices connected to the same bus.

Listed here are the main features for TWIM:

- I<sup>2</sup>C compatible
- Supported baud rates: 100, 250, 400 and 1000 kbps
- Support for clock stretching (non I<sup>2</sup>C compliant)
- EasyDMA

The two-wire interface can communicate with a bi-directional wired-AND bus with two lines (SCL, SDA). The protocol makes it possible to interconnect up to 127 individually addressable devices. TWIM is not compatible with CBUS.

The GPIOs used for each two-wire interface line can be chosen from any GPIO on the device and are independently configurable. This enables great flexibility in device pinout and efficient use of board space and signal routing.

Figure 220: TWI master with EasyDMA

A typical TWI setup consists of one master and one or more slaves, as illustrated in the following figure. TWIM is only able to operate as a single master on the TWI bus. Multi-master bus configuration is not supported.

Figure 221: A typical TWI setup comprising one master and three slaves

TWIM supports clock stretching performed by the slaves. The SCK pulse following a stretched clock cycle may be shorter than specified by the I<sup>2</sup>C specification.

TWIM is started by triggering the STARTTX or STARTRX tasks, and stopped by triggering the STOP task. After a STOP task, TWIM generates a STOPPED event when it has stopped.

After TWIM has been started, the STARTTX or STARTRX tasks should not be triggered again until TWIM has issued a LASTRX, LASTTX, or STOPPED event.

TWIM can be suspended using the SUSPEND task, such as when using the TWI master in a low priority interrupt context. When TWIM enters suspend state, it will automatically issue a SUSPENDED event while performing a continuous clock stretching until it is instructed to resume operation via a RESUME task. TWIM cannot be stopped while it is suspended, thus the STOP task has to be issued after the TWI master has been resumed.

**Note:** Any ongoing byte transfer will be allowed to complete before the suspend is enforced. A SUSPEND task has no effect unless TWIM is actively involved in a transfer.

If a NACK is clocked in from the slave, TWIM generates an ERROR event.

### 7.36.1 Shared resources

TWIM shares registers and other resources with other peripherals that have the same ID as the TWI master. Therefore, you must disable all peripherals that have the same ID as TWIM before it can be configured and used.

Disabling a peripheral that has the same ID as TWIM will not reset any of the registers that are shared with TWIM. It is therefore important to configure all relevant registers explicitly to secure that TWIM operates correctly.

The Instantiation table in [Peripherals](#) on page 149 shows which peripherals have the same ID as the TWI.

### 7.36.2 EasyDMA

TWIM implements EasyDMA for accessing RAM without CPU involvement.

TWIM implements the EasyDMA channels found in the following table.

| Channel | Type   | Register Cluster |
|---------|--------|------------------|
| TXD     | READER | TXD              |
| RXD     | WRITER | RXD              |

Table 75: TWIM EasyDMA Channels

For detailed information regarding the use of EasyDMA, see [EasyDMA](#) on page 153.

The RXD.PTR, TXD.PTR, RXD.MAXCNT, and TXD.MAXCNT registers are double-buffered. They can be updated and prepared for the next RX or TX transmission immediately after having received the RXSTARTED or TXSTARTED event.

The STOPPED event indicates that EasyDMA has finished accessing the buffer in RAM.

### 7.36.3 Master write sequence

A TWIM write sequence is started by triggering the STARTTX task. After the STARTTX task has been triggered, TWIM generates a start condition on the TWI bus, followed by clocking out the address and the READ/WRITE bit set to 0 (WRITE=0, READ=1).

The address must match the address of the slave device that the master wants to write to. The READ/WRITE bit is followed by an ACK/NACK bit (ACK=0 or NACK=1) generated by the slave.

After receiving the ACK bit, TWIM clocks out the data bytes found in the transmit buffer located in RAM at the address specified in the TXD.PTR register. Each byte clocked out from TWIM will be followed by an ACK/NACK bit clocked in from the slave.

A typical TWIM write sequence is shown in the following figure, including clock stretching performed by TWIM following a SUSPEND task.

A SUSPENDED event indicates that the SUSPEND task has taken effect. This event can be used to synchronize the software.

TWIM will generate a LASTTX event when it starts to transmit the last byte.

Figure 222: TWIM writing data to a slave

TWIM is stopped by triggering the STOP task. This task should be triggered during the transmission of the last byte to secure that TWIM will stop as fast as possible after sending the last byte. The shortcut between LASTTX and STOP can alternatively be used to accomplish this.

**Note:** TWIM does not stop by itself when the entire RAM buffer has been sent, or when an error occurs. The STOP task must be issued, through the use of a local or PPI shortcut, or in software as part of the error handler.

### 7.36.4 Master read sequence

A TWIM read sequence is started by triggering the STARTRX task. After the STARTRX task has been triggered, TWIM generates a start condition on the TWI bus, followed by clocking out the address and the READ/WRITE bit set to 1 (WRITE = 0, READ = 1). The address must match the address of the slave device that the master wants to read from. The READ/WRITE bit is followed by an ACK/NACK bit (ACK=0 or NACK = 1) generated by the slave.

After sending the ACK bit, the TWI slave sends data to the master using the clock generated by TWIM.

Data received will be stored in RAM at the address specified in the RXD.PTR register. The TWI master will generate an ACK after all but the last byte have been received from the slave. TWIM generates a NACK after the last byte received to indicate that the read sequence shall stop.

A typical TWIM read sequence is illustrated in the following figure, including clock stretching performed by TWIM following a SUSPEND task.

A SUSPENDED event indicates that the SUSPEND task has taken effect. This event can be used to synchronize the software.

TWIM generates a LASTRX event when it is ready to receive the last byte. If RXD.MAXCNT > 1, the LASTRX event is generated after sending the ACK of the previously received byte. If RXD.MAXCNT = 1, the LASTRX event is generated after receiving the ACK following the address and READ bit.

TWIM is stopped by triggering the STOP task. This task must be triggered before the NACK bit is supposed to be transmitted. The STOP task can be triggered at any time during the reception of the last byte. It is recommended to use the shortcut between LASTRX and STOP to accomplish this.

TWIM does not stop by itself when the RAM buffer is full, or when an error occurs. The STOP task must be issued, through the use of a local or PPI shortcut, or in software as part of the error handler.

TWIM cannot be stopped while suspended, so the STOP task must be issued after TWIM has been resumed.

Figure 223: TWIM reading data from a slave

### 7.36.5 Master repeated start sequence

A typical repeated start sequence is when TWIM writes two bytes to the slave followed by reading four bytes from the slave. This example uses shortcuts to perform the simplest type of repeated start sequence, i.e. one write followed by one read. The same approach can be used to perform a repeated start sequence where the sequence is read followed by write.

The following figure shows an example of a repeated start sequence where TWIM writes two bytes followed by reading four bytes from the slave.

Figure 224: Master repeated start sequence

If a more complex repeated start sequence is needed, and the TWI firmware drive is serviced in a low priority interrupt, it may be necessary to use the SUSPEND task and SUSPENDED event to guarantee that the correct tasks are generated at the correct time. A double repeated start sequence using the SUSPEND task to secure safe operation in low priority interrupts is shown in the following figure.

Figure 225: Double repeated start sequence

### 7.36.6 Low power

To ensure lowest possible power consumption when the peripheral is not needed stop and disable TWIM.

When the STOP task is sent, the software shall wait until the STOPPED event is received as a response before disabling the peripheral through the ENABLE register. If the peripheral is already stopped, the STOP task is not required.

### 7.36.7 Master mode pin configuration

The SCL and SDA signals are mapped to physical pins using the PSEL.SCL and PSEL.SDA registers.

The PSEL.SCL and PSEL.SDA registers and their configurations are only used as long as the TWI master is enabled, and retained only as long as the device is in System ON mode. When the peripheral is disabled, the pins will behave as regular GPIOs, and use the configuration in their respective OUT bit field and PIN\_CNF[n] register. PSEL.SCL and PSEL.SDA must only be configured when the TWI master is disabled.

To secure correct signal levels on the pins used by TWIM while in System OFF mode, and when TWIM is disabled, these pins must be configured in the GPIO peripheral as described in the following table.

Only one peripheral can be assigned to drive a particular GPIO pin at a time. Failing to do so may result in unpredictable behavior.

| TWI master signal | TWI master pin                         | Direction | Output value   | Drive strength     |
|-------------------|----------------------------------------|-----------|----------------|--------------------|
| SCL               | As specified in PSEL.SCL <sup>31</sup> | Input     | Not applicable | S0D1 <sup>31</sup> |
| SDA               | As specified in PSEL.SDA <sup>31</sup> | Input     | Not applicable | S0D1 <sup>31</sup> |

Table 76: GPIO configuration before enabling peripheral

<sup>31</sup> Special pin and drive strength considerations applies when using the 1000 kbps baud rate. For pin recommendations, see [Pin assignments](#) on page 851.
